 Second .
 it's never a good idea to have full out put in CW....90 watts is plenty and if your using a tnc,
  the lower the better. I only run 30 watts max in CW on any band,,,,,,,,,,,,
and about 20 max on digital modes.
RF could very possible the culprit.
73, good luck

On Friday, December 27, 2013 9:15 PM, ko6r <ko6r@yahoo.com> wrote:

I hope, even though the Z100 is an old model, that someone can give me some ideas about what happened to me today.
I was on 15M with my FT-897 running 100W, and had tuned up using the Z100 quite satisfactorily. In the middle of a CW QSO, my radio went belly-up, did a complete reset, blanking out all my memories and resetting my menus to default values, but it stayed powered up!
Luckily I had used CHIRP a few months ago to make an image file of the radio's mems and menus, so I could upload that and get back to normal. But I'm mystified by what happened: suddenly the swr indicator on the radio went full scale, and blammo!
Googling brought a suggestion that perhaps some RF got from the tuner into the radio, since the tuner sits right on top of the rig. I don't really have any idea what happened, and as soon as I recovered from the shock, I got back on frequency, retuned and carried on as I had been previously. No subsequent problems.
Any ideas or thoughts or flashes of insight very welcome.

Thanks in advance,
Peter KO6R

Peter,

I have the LDG1000ProII so I do not have the same setup. It does seem strange to me that the SWR indicator would peg and the radio reset with just 100W out. My linear, tuner and exciter are side to side (touching) in a row, left to right. I have had more than one “senior moments” where I forgot to put the linear in standby before re-tuning to a different band/freq. I have both an FT-950 and an FT-857D and have never had this happen. At your 100W, I doubt seriously enough RF got into the rig to cause this. The main result from stacking equipment is the fans staying on due to heat buildup.

If it were me, I would momentarily go key-down (or send dashes) and wiggle all the coax jumpers and power leads. The jump in SWR could also be from a momentary incident with the antenna such as an arc or limb. I once had a heck of a time with a RG-8X jumper that had a single strand of braid rattling around in the PL-259.

Another situation that might apply is a problem with your station grounds.

Good luck es 73, Bill – K4IZE

I think you're right, Art.
I will for sure dial it back to a max. of 50W, and perhaps less, once I find out how I'm getting out.
As for the stack, hmm...I have to look at that. Space considerations in a rather cramped corner.
Thanks for your thoughts.

Where should I add a Bencher LP filter to my Icom 746Pro and AT200ProII ..

Should the path be:

746Pro to Bencher Filter to AT200 to Antenna

or

746 Pro to AT200 to Bencher LP filter to Antenna

Thanks..

Rick N9AJ

Should probably go between the radio and tuner as filters are designed
to work into a 50 ohm load. Exception would be if the filter doesn't
provide a reasonable 50 ohm load then it should go between the tuner and
the antenna.

Hello, Does the AT 600 Pro II have a memory backup battery? How long will it last with the power supply turned off? Or should I leave the supply turned on?

For backround info, I have it connected to the Elecraft K3 line, without a tuning cable, and it works great!

Happy New Year!

Hello All,

I seem to be having something of a recurring problem with my Z817.

In short when I press the 'Tuning' button, by either holding the button down until the red light goes out, or momentarily, the rig will go into Tx but not switch into Packet mode.

The end result is that a few seconds later the error light will flash and the rig will go back into Rx without the Z817 tuning properly.

The only solution I've found is to turn the rig off and on again, this seems to clear the fault.

I've checked the baud rate and all of the connections on a number of occasions and everything seem to be fine.

Has anyone experienced this before or have any thoughts?

Thanks in advance for any help.

Kind regards,

Sean.

Sounds like a fault in the FT-817 rig, not the tuner. You ARE using a Yaesu 817 rig, are you not? You ARE punching the TUNE button on the rig, are you not?

Hi Prasad,

You can run, but you can't hide (from me). I researched the same question before I bought my LDG-1000 ProII. My conclusion was that they are very different animals doing the same job mostly the same way. The obvious difference is the LED bar graphs for power and SWR. One less meter to read with my old eyes! According to LDG, a lot of internal "improvements" are also in the ProII.

I am happy with mine except for the limited power for actually tuning. I cannot "auto-tune while running high power. No big deal – just put the amp in standby and do a quick auto-tune with just the exciter. If I had to do this again, I would stick with the ProII. My old peak reading Swan meter went bad after 30yrs so I plan to buy the optional add-on meter for the 1000ProII. 73,

Bill

Hi Prasad,

The Pro II has an Ant2 LED and a Bypass LED so you can see at a glance which antenna is in use and if the tuning circuit is switched in or not.

Regarding operation/firmware, I guess it differs to control those 2 LEDs but I am note sure if there is a performance gain in the MK2 version.

I am in a quandary. I had an LDG 100Pro with my IC-7000 and have a LDG AT-600 proII both past and present worked great.

I am now looking for a tuner for my KX-3 and Hardrock 50.

I was looking at Eham reviews and surprised how many people speak so badly of the LDG product line.

Anyway I plan to use different wire antennas, verticals.

What does the group recommend? I was leaning to the Z 100 Plus but after reading last night might go with a Z 11 Pro II.

Help clear an old fellows head.

I've had nothing but great results with both of my LDG auto-tuners.
Those who complain are generally folks' who don't read the manual,
or they're trying to get it to tune while running maximum amplifier output,
or they're trying to tune a barbed-wire fence or rain gutter, etc.

I've not only had fine results with LDG products, I've had amazing personal support when I needed help. I'm talking about back and forth emails that offered suggestions, including some that were only tangential to the product - advice that let me do a better job with my station. I've never seen that kind of support from any other company - ham or consumer.

I now own two of the tuners and have owned, over the years, at least that many more.

Topic: 6646 Message: 6649

I have several different models and all have worked well. If I was shopping tomorrow I would buy another without any hesitation.

I run about 100 watts max with no amp.

Reading between the lines I think some folks are expecting a little too much!!! You should make an effort to get your antenna as close as you can prior to expecting a tuner to tune it.

With some common sense the LDG tuners have a wide range and will probably tune some things you should not try and tune.

Good Luck with your project.

Subject: Re: [LDG-auto-tuners] Tuner for my HRD-50

I've had nothing but great results with both of my LDG auto-tuners.
Those who complain are generally folks' who don't read the manual,
or they're trying to get it to tune while running maximum amplifier output,
or they're trying to tune a barbed-wire fence or rain gutter, etc.

Subject: [LDG-auto-tuners] Tuner for my HRD-50

I am in a quandary. I had an LDG 100Pro with my IC-7000 and have a LDG AT-600 proII both past and present worked great.

I am now looking for a tuner for my KX-3 and Hardrock 50.

I was looking at Eham reviews and surprised how many people speak so badly of the LDG product line.

Anyway I plan to use different wire antennas, verticals.

What does the group recommend? I was leaning to the Z 100 Plus but after reading last night might go with a Z 11 Pro II.

Help clear an old fellows head.

Bill--
IMHO—Anyone that relies on EHAM reviews is looing at a mixed-up mess. There are too many people with questionable motives on there to have reliability. Over all, what I read of LDG is pretty good, and I read a lot of good things about their support. My own (second hand) LDG AT100 Pro II has worked well for years.
YMMV

6651. KT-100 Remote Panel advice

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-01-19 00:28:28 UTC
From: Avery
Topic: 6651 Message: 6651

What would I need to do to build a remote panel to duplicate the front panel of the KT-100? This is so I can install the KT-100 remotely from the operating position. It was easy to extend the AT-300 control cable so it works well remotely from a Kenwood transceiver - except on 6 meters, due to limitations on the Kenwood transceiver. The manual does not include a detailed schematic of the tuner, so I need some advice on how to build a remote panel for the KT-100.

Thanks!

Hi Bill..

I have a Z11 Pro and it has worked great with every rig I've uses it on..

That includes with a KX3 and RM Italy amp.. I had the KX3 tune button set to 1.5 watts.

The Z11 Pro (II) will tune when you send a carrier to it.. (no interface cable required) It takes less then a watt to tune. The buttons on the front let you manually touch up the tuner if it does not get as good a match as you would like.

It.should work fine for you.

From: David Birnbaum
Topic: 6654 Message: 6654

Is there some way to have my RT-100 switch to bypass mode where it just connects the input to the antenna?

I want to use this for the times when I use my rig to cover non-ham band SWL. When it's tuned for one of the ham bands it reduces the signals that are out of band.

Hi Avery,

I have the YT-100 which is a simple 3.5mm stereo connector to wire up a switch, but consulting the manual for the KT-100 I see no such facility, only rig control. You can extend that cable though as detailed on page 15 of the manual. Good luck.

Mike,
Thanks for the reply. I have extended the rig control cable, and it works well, but the problem is the firmware in the radio thinks that it is connected to an AT-300, and since the AT-300 won't work on 6-meters, it won't allow external antenna tuning on 6-meters even though the KT-100 works fine on 6-meters. So, I have to manually push the tune switch on the front panel of the KT-100 if I want to tune an antenna on 6-meters, and since I mounted the KT-100 near the body of the TS-480, it is not within reach of where I have mounted the control head of the TS-480. Thus my desire to remote the front panel tune switch which is normally redundant on the KT-100. The KT-100 works great using rig control on lower bands.

I am hoping that someone who has modified a KT-100 for an external tune switch will give me some pointers on how best to do this.

Avery, this might be me teaching grandpa to suck eggs but in the tuner manual:

When using the KT-100 with a TS-480SAT, hook the KT-100 to the ANT 1 jack of the TS-480SAT. Set menu #27, “EXTERNAL AT OPERATION MODE” to “At1”. You will have to power off and back on for this setting to take effect.

Also, when you are on 6m, is antenna 1 selected as well?

The TS-480 manual says: If you want to use the external antenna tuner,AT-300 with the TS-480 transceiver, access Menu No. 27 and confirm that “At1” is selected(default). “At2” is reserved for future update.

I wonder if At2 has the command set but without the 6m limitation?

Worth a try I guess?

The only other suggestion would be to modify the KT-100 to have an external switch so you can run a new switch to your operating position, a simple mod I expect, just a wire from the existing switch connections with a switch on the end of it. To make it really smart, a case mounted 3.5mm socket to disconnect the external switch, or change its length.

But I wouldn't do that until speaking to LDG via email or phone as they might have a solution. Sorry I can't be more help. I hope you get a solution.

Topic: 6663 Message: 6663

I took the new RT100 that I had been using for the past couple of weeks out of the feed line last night to try another tuner. When I put it back in it acts like it is tuning on the 6 and 10 meter bands; but, ends the cycle with the highest SWR and not the lowest. It doesn't appear to be tuning, when I try on the lower bands as it the SWR meter stays maxed. Temperatures here were in the mid-20's when I was working with it last night. It was not working this morning with temps in the high teens. I have checked all the connections, several times, and it is hooked up correctly. Any suggestions?

Topic: 6664 Message: 6664

I have a one year old AT-600pro. About 2 months ago it started this thing where the pwr and swr bargraph quit working during tune and transmit. I could unplug the tuner and plug it back in and the problem was fixed. As of yesterday the problem is permanent. The Bargraph lights work if you do something like press the tune button for a full tune, but transmit and tune they are dark.

I know I'm still under warranty, and I sent LDG a e'mail. I was hoping there is some simple cure for this as I had some quality radio time planned for this weekend and I suspect I won't hear from LDG until at least Monday.

Thanks Hank AB2XG

If your LDG Z100 is like my LDG AT-1000pro11.....
  The function then Store buttons means you have
changed the auto tune setting from1.5 to 1.7 and on up
the scale.
  You can set the auto tune function from 1.5 to 3.5 on the Pro 11.
It's in the manual for my 100 Pro 2.

On this tuner I think I that function you're talking about is threshold. That is another button on this one. The store button is a secondary function of the tune button on this one. I've pushed the threshold button and the lights show the progression up like you're talking about.

Hi Mike,

Thanks for your input.. I'm not sure if that would be an option for all other Yaesu radios but something to look at.

I see that the FT 950 has a remote jack for the FH-2, so this is possibility a way to simplify auto tuning.

I have rewritten my post on using the remote jack adding more information and fixing a couple of errors.

I hope we can get some feed back on this, maybe LDG will take a closer look at it.

73.. Ken - VE5KC

6676. Use LDG tuners -> Yaesu with Remote connector (rewrite)

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-02-04 09:54:51 UTC
From: <ve5kc@...>
Topic: 6676 Message: 6676

After reviewing my previous post I decide to rewrite parts of this.
I have also included links to where I obtained this information.

Maybe LDG will look closer at this and update their information on using more Yaesu radios.

Yaesu has not been good with providing information with some of the interfacing to radios. I suppose they are hoping you will buy abd use only their accessories. Because of this, we do not know for sure if the use of the remote jack will work on all models.

I searched for information that may answer to this and here is what I have found:

This is suppose to apply to Yaesu rigs that have a remote jack and can use the FH-1 or FH-2. (MFJ - see below)

If your radio has this remote jack, you should be able to connect your tuner and use the tuners tune button. (The FH-1 had a tune button) This should also works for sending a carrier to tune an amplifier. (A menu item on some models lets set the power output for this function)

The remote jack functions depend on the value of resister in series with the center connector of the mono jack connected. This is how the FH-1 or FH-2 remotes work. To use this for the tune function you must use a resister value of 2.5K ohms.

With this cable connected to your tuner, pressing the tune button, on the tuner, should start the tune cycle. Another option for some tuners would be to connect a cable with a switch to the radio, to send a carrier for activating a RF sense tune cycle.

Because the remote jack function is based on the resistance switched into the circuit and is open when no button is pressed, you can use an adapter that lets you connect the tuner and the FH-1 or FH-2 at the same time. MFJ sells a cable (MFJ-5124Y3) for some tuners for connecting to the remote jack. (might work with LDG?) - see below

I don't have a Yaesu transceiver but am looking at buying a FTDX 3000. I also have a friend with a FT 950 who could benefit from using a LDG tuner but must have a simple way of operating it.

I hope that LDG or someone in the group can check this out and report back.

Reference information:

MFJ sells a cable for their auto tuners - MFJ-5124Y3

"The MFJ-5124Y3 cable connects your MFJ-991, MFJ-993, or MFJ-994 Intellituner to your supported Yaesu radio. The cable supports: Yaesu FT-1000MP, FT-1000MP MKV, FT-1000MP MKV Field, FTDX-9000, and any Yaesu radio compatible with the Yaesu FH-1 or FH-2 Remote Control."

Using the "Remote jack" to tune amplifier - (Yaesu VL-1000 Amplifier manual)

Automatic Amplifier Tune-Up using FT-1000MP Transceiver

When using the VL-1000 in conjunction with the FT-1000MP transceiver, the front panel SET key may be used to initiate an tuning procedure for the amplifier. In order to accomplish this, Menu Item 7-9 on the FT-1000MP must be set to “KEYER” (which is its default value), and a control cable must be connected between the FT-1000MP’s R EMOTE jack and the VL-1000’s BAND-DATA 2 jack. The required wiring for this cable is shown below.

From the amplifiers Band-Data2 connector, Pin 9 connects to ground and Pin 10 to the tip of the remote jack.

6677. Problem with CAT Control

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-02-04 03:49:19 UTC
From: <ditloyd@...>
Topic: 6677 Message: 6677

I recently purchased a YT-450 AutoTuner for use with my FT-450 and rig control software. I am unable to use any rig control software. I have tried Flrig, Ham Radio Deluxe (HRD) 5 and HRD 6.
Flrig, HRD 5 and HRD 6 work perfectly using the FT-450 internal tuner. The FT-450 and the YT-450 work perfectly together without Flrig, HRD 5 or HRD6 running.
I’m having the exact problem with all of the above rig control programs....
When using SSB at 100 watts output, I press the tuning button on the YT-450, the tuner completes a tuning cycle and will leave the rig set in AM mode and the RF power set at 50 watts. Sometimes I will find the mic gain set to low.

What I find unexplainable is, when the event above takes place, you can shut down the rig control software completely (no rig control running), manually change the radio back to SSB and 100 watts output, press the tune button again and the Tuner will cycle through a tune cycle and continue to leave the radio in AM mode and set at 50 watts after each tune cycle. This problem will persist until you reboot the tuner by disconnecting the power and powering it back up.. At this point the radio and turner will work perfectly together as long as you do not start up HRD or any rig control software.
I have tried multiple rig control programs, I have tried every combination of setting on the radio and software and computer port you could imagine. I have completely reset the Yaesu to factory defaults. Installed the latest Yaesu firmware. I have tried a different CAT cable.
It appears the tuner is releasing the CAT port back to the computer before it has completed its cycle and instructed the radio to change back to its prior mode and RF output settings.
Anyone else have this problem?

6678. Re: [LDG-auto-tuners] Problem with CAT Control

From: Brian Denley
Topic: 6677 Message: 6678

Yes I have had similar issues with my YT-450 and my FT-950. Once in a while the YT-450 gets in a mode where it changes my TX output to 50 watts (from 100) and changes my AM carrier output up to 100 watts (up from 50) whenever I do a tune. I never connected the problem to using HRD and I do use that software. The problem has gone away for now but always returns at some time.

6679. Should work fine, Re: KT 100 used on other rig.

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-02-05 04:48:18 UTC
From: Avery
Topic: 6672 Message: 6679

Yes, it should work fine, just follow the directions in the manual for using the tune button and the two LED indicators. I tried this out with my KT-100 when I was having trouble with the remote cable I was building, and it worked great. Since I got the remote cable fixed, I haven't used the tune button as it works great from the control head of my TS-480. I have uploaded pictures of my mobile station with the KT-100 in a photo album on this Yahoo group, so you can take a look.

Hi MIke,

I'm beginning to think it is more of a mechanical failure rather than an electronic one.

I've so far found that when this happens that it has something to do with the connector cable between the Z817 and the rig. Simple pressing on the connector at the back of the rig, the ACC socket, and pushing the connector slightly more firmly into the socket seems to clear the fault and the tuner will operate normally.

Need to have a closer look at it but beginning to suspect a doggy connector / cable.

Hope this helps.

Sean.

I spent 2 solid weeks chasing a CAT problem on a series of FT-8x7 radios I
was testing. The could hear CAT signals, but they were not echoing back.

Turns out it was the pin on the cable end had slid back about 1mm and was
making intermittent connections.

That was last week.

I had a similar problem years ago. When I had intermittant tuning problems, my dealer initially replaced my Z-817 with a Z-817H which was better but still had problems. In the end Yaesu authorised a replacement of the PCB and all was well. It turned out there was an issue with the FT-817 and it was easier to replace the whole board than to fault find.

Hello Rob ...

I am a K3 owner/user and very new to this group, so I'm not an expert.
Nothing special in the hook-up. I have two antennas, a SteppIR vertical and a OCF windom. I used antenna position #1 on the K3 and connected the
two antennas to the back of the ProII. I've found I can use the "Tune" feature
on the K3 to shoot a few watts down the line to tune the tuner. I have a question or two abt the operation of the 600ProII, but I'll pose that in a seperate note.

New to the group but an old user of LDG products. Have received my RT-100 and RC-100 and read the manual before pressing forward with stealth antennas. The manual states that a regulated 12 VDc 500 ma power supply is recommended but is not required. Has anyone had experience with the ubiquitous wall warts. A typical 12 volt 500 ma unit gives about 16 or more volts at no load dropping to 12 volts at the spec 500 ma. Would appreciate any input before powering up, many thanks, Keith, VE3JKC

Using walwart with some products in ldg product line causes numerous operational problems,try a good quality power supply only or aux 12 dc from your rig.

LDG may have a list of wallwart products they have found that work

Can you elaborate which rig your going to use

The numerous number of complaints in this blog on this walwart issue . if you can avoid the walwart issue do so it should be a lots less troublesome

My older kenwood TS 50 has a tuner jack that has 12 on it to power a tuner.

My dc power source is also a12v battery to provide emcomms operation off gird so one can operate in a disaster.

Think of the recent 10 day toronto power outage and wider southern ontario outage a fomer Ontarioite living in VE5 and VE7 land.

I was in ontario for both major power blackouts in 1965 and 2004 approx so i know from 1st hand experience what happens

Many thanks for the replies. The situation that precipitated this request for info goes back to a downsize and condo relocation, so stealth antennas are the name of the game and when LDG announced the remote tuner I ordered one as a possibility for my situation. I do have a few "good" 20 amp supplies and my Omni VII does have an Aux 13.8V 500 ma accessory connector.
However It's power supply, unlike my Icom that I sold that had three accessory connections, does not have accessory connectors. So the situation is that for a clean set up all my Aux connectors are taken. I have used the wall wart with success on other items such as my Autek WM-1 wattmeter, but it came that way. Also I have opened them up and installed a three terminal regulator .
So the bottom line was I just wanted to see what the "other half" was using before I came up with another set of connectors on the existing rig. I would like to thank you all for taking the time to reply to my posting and sharing your thoughts and experiences. Best 73's, Keith, VE3JKC. ex VE2ANC (1950).

Topic: 6687 Message: 6692

It depends what type of wall wart it is.

Older wall warts with transformers were seldom regulated and if they were, it was pretty crude.

If however your wall wart is a newer, lighter, smaller, switchmode unit then you should be fine. I gave up on unregulated wall warts a long time ago and now only use the switchmode version.

Also. If you're handy with veto board, you could crack open a transformer wall wart, rip our the internals and make your own bridge rectifier, ripple cap and a simple 7812 regulator and problem solved :)

6693. Anyone have a JT-11P Jupiter Auto-Tuner available?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-02-24 05:10:24 UTC
From: <vtat1271@...>
Topic: 6693 Message: 6693

Curious if anyone has a JT-11P auto tuner for the Ten Tec Jupiter laying about. I realize it's unlikely as these were permanent-install internal auto-tuners. But I've got a Jupiter with no tuner in it, and I'd prefer to put an LDG unit into it versus buying the factory's auto-tuner.

Please email me directly off-list if you have one. My email address is surf_boy82@yahoo.com if it's not listed.

Thanks,

Chris/KF6AJM

6694. Ferrite material in RBA transformers

From: <g4bbh@...>
Topic: 6694 Message: 6694

Due to accidental use at 100W with no antenna connected the core in my RBA-4:1 has cracked so a rebuild it necessary. My first accident in about 8 years of use. I know it is an FT-125 but not sure what material it is - possibly type 43 or it could be type K? Fortunately I photographed the internals some years ago so can see it is 14 turn bifilar and the connections tally with the manual. Just need to know what core material is needed if anyone knows.

What colour is it?

I suspect that type 2, 43, 61 or K would work, but I am guessing.

This seems to be plain dark grey or black unpainted ferrite. Looking at my Amidon catalogue I see the T125 size is only listed in type K so guess that must be it. Not going to be so easy to obtain type K as type 43. TYpe K has an initial permeability of 290 compared to type 43 with .an initial permeability of 850. I'm not sure if Amidon colour their ferrite cores anyway. I know the iron cores are coloured, for example I use a lot of type 2 (red) iron cores on HF.

Back in the good old days LDG published the manuals with parts lists for their products. The then BA-1 4:1 Balun manual had a parts list and it then used the T-130-2 (Amidon etc.) which was a red colored core. I think that they have since changed to a ferrite core but I don't know the spec. I built one with a T-200-2 and while it works it is not as good as 2 Wireman bead baluns in a 4:1 true current configuration that I built later . Good Luck, Keith, VE3JKC.

We got our design from the Sevick transmission line book. At the time, about everyone was making 2KW baluns, So we scaled the design down to 200 watts for 100 watt applications.

Would be interesting for sure.

Most low band antenna are not flat across the band especially on 80
(unless it's a SteppIR).

Most triband beams are not flat across 20 (unless it's a SteppIR).

If I had not just bought one, I would take you up on this offer. That said, unless $$$ is a priority, you might want to hold on to it. Except for the Stepper line I have seen very few “resonant” antennas with any gain or good front-to-back that cover entire bands. I have mostly tuned Yagis and am surprised at the recv gain I get from fine-tuning with the 1000Proll. I can only assume that it helps on xmit. Most antennas are pretty narrow-banded.

Good luck es 73,

Bill

For Sale:
LDG AT-1000 PRO II Tuner (Latest Model with Latest Firmware)
Original Box
Original Packing
Original Manual
Original Power Cable

This unit is in like new condition (mint mint mint). I purchased it August 2013 paired up with my FTDX3k and my AL-80B amp. I already have on order a resonant antenna thus this is now excess to my needs. I have the original receipt if you would like to have it.

Price: $365 + shipping

I have a Carolina Windom 80 and it does a great job of covering the advertised bands including 30, 17 and 12 meters. I get consistently good performance.

Will be curious as to which one he's getting.

Re: Z11-PRO II

The only spec that changed is the operating voltage. It's now 6 to 16 volts at 300 mA. That allows 4 AA batteries to power it for about a year. You can even use a 9V battery for a weekend or two.

From: David Birnbaum
Topic: 6715 Message: 6716

I've got my RT-100 at the base of a 21 foot vertical with a 2' top hat loading. The RT-100 will tune it on all ham bands 80m and up, most to essentially 1:1, although it gets to 1.5:1 on a few places.

My only reservation is to limit my power on 80 m because my calculations show about 20% loss in the tuner (the reisistance is quite low and very capacitive on 80). I have some concern about power loss on 40, but I run 100w max so that's not likely to be a problem.

Topic: 6720 Message: 6720

Doesn't make sense, but tried it anyway. Shortened antenna by 1 foot; no change. Very narrow bandwidth is what's weird; OK (1:1) at 14067.5 or 14082.5 but way high between 070 and 080. Even if I tune it at 067.5, SWR jumps as soon as I go up. Also tuner finds lower SWR setting but continues until settling at higher SWR.

6721. KT-100 on a Yaesu FT-897D

Leonard replied “Won’t work...” and he might be correct but he doesn’t provide any details as to why he is adamant about it. If it were me I would try applying power to the KT-100 via the ground pins (quan 2) and the +12vdc pin as per the picture on page 15 of the manual. I would construct the simple cable/switch to use on the FT-897/857 that puts the radio into “Transmit Request” cw mode and see if the tuner tries to tune by rf sensing (see ACC jack on page 18 of FT-897 manual). If not I would press the tune button on the tuner while still pressing the button on the radio and see if it tunes. You only loose a little time and won’t hurt anything.

Since the FT-897 can be battery operated portable I recommend the LDG Z-11PROII. It runs on batteries or an external 12vdc power source, handles .1 to 125 watts and can be used with any radio. You won’t be locked into a specific brand radio with this tuner.

Good luck and let us know how you make out if you try my suggestion.

I use the kt-100 on my 857d. You need to make a power cable to provide 12v. Switch the radio to 5 watts and AM mode and follow the manual tuning directions for the kt-100. The radio is only connected to the tuner with the antenna connections. You are not using CAT control.

I have an Alpha Delta Pathfinder. I think it is still working ok, but I am not getting the bar graph or the numerical indication of the SWR on the LCD panel.

It was working and I really have not been using the tuner much etc.

I know this unit is old and not supported anymore, but just wondering if any has any idea of where to look on the circuit board.
I read an older post on this group today and replaced a couple of diodes, but to no avail.

With help from Albert, and investigation from myself, this is how its done.

With 10 watts forward power at 14 MHz adjust the cap for minimum voltage on REV test point (I got 10mV) then you set FWD pot to give 3 volts on the FWD test point.
Then reverse the TX and ANT connectors and adjust the REV pot to give 3 volts on the REV test point.
I then connected a dummy load of 25 ohms this will give a SWR of 2 to 1. the amber LED lit indicating a SWR 2.0

That is how I found mine was set-up, and that's how I remembered it to be.

As was said earlier try changing the antenna feedline length - This may have more effect than changing the antenna length. I also have a RT100 and so far it has worked excellently. This past week I took it on a trip to N Dakota to visit my stepson. His apartment was on the third floor. I used an alligator clip to his window frame for one side of the antenna, set the RT on the ledge and just dropped the wire outside the window for the other side. Have no idea where it was resonate but it tuned up clear across the 40/20/15/10 meter bands without a hiccup.

I don't know if this "issue" has been discussed or not.
I have an LDG AT1000Pro11 that I have had for about a year now,and

after it tunes,my noise floor is at least a seven or eight on my
YAESU FT 857D.

If I turn the tuner off,the noise goes away,and the SWR goes back up.
Sounds like there RF coming from the tuner itself .
The power supply is on the floor about two feet away from the radio and
tuner,and I have a power strip that feeds the 12 volts to the radio
and tuner,and external meters . I also have ferrit beads on all power

leads .I might add that the noise is not just limited to a few bands,
but all from 10 to 75 meters .
I bought this tuner new,and the noise has been there the whole time.
Anyone else have this "issue " ?

It depends if the noise level increase is due to power supply noise of just best antenna matching.

My noise level goes up significantly when the tuner has a good match as opposes to a bypassed bad match, especially on the lower bands. I'm using a 43' vertical. I think you can tell is this is the case base on Signal to Noise ration. A bad match will have the same S/N, just a lower level.

The only other noise source likely is from the power supply. If you think that might the source, try a 1 amp or better 12 volt power supply. Some say wall warts have been noisy (mine is fine).

It's most like just noise on the band because of a good match. SWR works both ways on receive and transmit. Try disconnecting the antenna with the power supply on and I bet the noise goes away. Unless the antenna is right next to your house it will show the noise is just from the band and due to a better match.

Does it look similar in size to C29 and C31? If so, it is the same as those, 0.01uF and you can get the voltage rating from the other ones.

Considering where it is in the circuit, there may be other damage. Did you have a lightning strike?

Okay.... to my surprise I emailed LDG about 20 mins after 5PM eastern. I quickly got a response back from Dwayne. He said that C30 was 150 pF.

The closest that I can find in the junk box is a 220pF. The only thing is, I don't see a voltage rating for the 221 cap. If there is no marking for voltage tolerances, what would be the expected rating since its not marked. I think that I need at least a 500V rated cap.

So what would a 221 tolerance indicate since there is no rating or marking ? And do you think the plain ole 221 will suffice?

FYI C29 = 82pF, C31 = 330pf @ 1Kv

Thanks again

Roger

Looks like you have a different PCB version than I do. Those value progressions seem to indicate they are the RF tuning capacitors (each step is approximately double) so you probably should find a 150 pF. I don't know the voltage rating.

Looks like you have a different PCB version than I do. Those value progressions seem to indicate they are the RF tuning capacitors (each step is approximately double) so you probably should find a 150 pF. I don't know the voltage rating.

On May 2, 2014, at 8:15 PM, <ki8du1@juno.com> wrote:

Okay.... to my surprise. UN. Nbbno bin. Boo no b. Bbmk. Ibinm nah. n n. Bmm v mm mmnmv, hmm cm up. K. Uu bmp Chinook non mm mm,bi. Noon n uvnnk mm ? Cm.n. no. Nmo I emailed LDG about 20 mins after 5PM eastern. I quickly got a response back from Dwayne. He said that C30 was 150 pF.

The closest that I can find in the junk box is a 220pF. The only thing is, I don't see a voltage rating for the 221 cap. If there is no marking for voltage tolerances, what would be the expected rating since its not marked. I think that I need at least a 500V rated cap.

So what would a 221 tolerance indicate since there is no rating or marking ? And do you think the plain ole 221 will suffice?

FYI C29 = 82pF, C31 = 330pf @ 1Kv

Thanks again

Roger

Well I found a 220pF 1kv cap from the junk box closest to the value that I could come up with and installed it. It didn't fix the tuning issues of the auto tuner. How ever it does work ok on 10 mtrs.

On a couple other bands it will tune up (good swr) but as I continue with a dead key up, the swr steadily/slowly increases to (too) high SWR readings.

So its looking like there is another issue of a component breaking down somewhere . :(

I've searched for other components for warming temps but could not find any others heating up.

I did not see any other visual indications of component failure so I guess I'm just out of luck. LDG will not send a schematic :(

Guess 'm outta luck

Roger

You really should get a 150pF and try it before you write off the tuner. The progression of the tuning capacitor chain is approximately doubling the value on each leg. The 220pF is close to triple the value of the one below and only 2/3 of the one above. This could be confusing the tuning algorithm.

Maybe LDG will send you one if you ask?

6748. ft-817nd for sale!!

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-05-05 00:25:59 UTC
From: <mbled2@...>
Topic: 6748 Message: 6748

hello group

I am selling my barely used yaesu ft-817nd. included in the auction are: yaesu 817nd with original box and documentation, rt systems version 4 programming software cd, rt systems usb-62b programming cable, extra yaesu e-dc-6 power cable, original hand mic (mh-31), original ac adaptor (pa-48b), original rechargeable battery (fhb-85), AA battery tray, original rubber duck antenna with both long and short tips, original carry strap, the after market peg-leg kit has been installed, the yaesu txco-9 has been installed, the w4rt collins mechanical 2.3khz filter has been installed, this radio was purchased in may 2013 with the hopes of joining me on a back packing trip however that never happened and i used it mainly as a bedside shortwave receiver, i have not transmitted on hf due to not having a tuner. the radio has always been in a non-smoking environment, the serial number is: 3e230842. THERE IS A SCRATCH ON THE TOP CASE COVER LID PLEASE SEE PHOTOS, when removing screws to remove the top lid and install the optional filter the screwdriver slipped, i was bummed as this happened on day one i had not even powered it up yet, other than the scratch the radio is in excellent condition. item is sold as-is no warranty, no returns, no refunds, item is shipped only to addresses in the 48 continental united states, payment via paypal only, SHIPPING IS FREE!! If the winning bid is with the "buy it now option" or the winning amount is above the $800.00 buy it now price i will include the pictured fun cube dongle pro + at no extra charge.

please copy/paste this link to view the auction:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=261472028759

or search ebay for item number: 261472028759
thank you and 73

6749. YT-100 with Yaesu FT-857D and RT Systems USB-62 cable

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-05-08 16:35:11 UTC
From: <rds@...>
Topic: 6749 Message: 6749

Hi,

have a problem with the combo above.

The YT-100 is connected with the FT-857D via the CAT cable. Tuning without no problem, everything is ok.

If I connect the RT Systems USB-62 cable with the Computer port at the YT-100 the Tuner doesn't work anymore, means no tuning cycles.

I have this problem too even if the software is not running and the cable is not connected with the compuer.

Any idea ?

Many thanks in advance

Rolf

Just to make sure, is the tuner installed on the output of the amplifier
or between the radio and the amplifier?

What bands and what kind of antenna are you using?

Yes its installed correctly after the amplifier doublet aerial plugged
into the AT-200 PR0 11 TUNER....Is it possible the amplifier is putting out
something it should not be ?????
IF i key up 150 watts out after tuning on low power 7 watts am the
reading is 2.1 swr in this state can i using the front controls on the
tuner to reduce this high swr????
thanks jim tylee g4rek

Jim:

Good on the installation and antenna.

My next question is what are you using to measure the SWR and is it sensitive enough for good reflected power readings at 8W forward power? A 2.1 SWR at 8W forward is less than a watt. Some SWR meters don't read that so well. If your reflected power is below the detection level at low power, then it will read 1:1 and as you increase power and get to the point where the reflected power is being properly detected, you'll start to see higher SWR indicated.

It is possible, however, that there's problems with your antenna, balun, feed-line and such that would cause the effective tuning of the antenna to shift slightly at higher power. However, you should look at your measurements first.

Messing with the tuner solution at high power will put additional stress on the relay contacts and may not be advisable unless the tuner is rated for tuning at that power level.

Hi All,
I'm new to the group. I've search the forum but haven't seen my question. If it's around please provide a link. Thanks.

I'm in a planing stage for building a remote operation station away from the base shack. I'd like to be ale to remotely tune and switch between antennas. I have an FT-857d and using Ham Radio Deluxe on the base station laptop. I'd like to be able to log into my station from other QTH's and be able to switch and tune antennas. Hope that makes sense.

Anyway, I'm interested in the AT-1000PROII because it can tune when it's keyed. However, it only has 2 antenna connections. I'm looking at the RCS-10L also.

Can the AT-1000II and RCS-10L be linked somehow? Does LDG have another devise that can link to the AT-1000II to offer more switching option?

Thanks - 73,
Joshua

Hi all,
I recently purchased in Italy the above AT. While the shack was unattended by me, for a home emergency, the computer started transmission, for a Ham Radio Deluxe malfunctioning or any other mysterious reason, and the rig ic718 continued to transmit for 15 minutes. When I went back to the shack, the AT was very hot, smoking a bit, and the rig as well. Switched off at once, after one hour switched on again, and it worked, but with a very bad smell. For few days I used it, but the smell was increasing, so I decided to give a look, openng the box.
One toroid was completely burned, but still working even if with a big resistance, and therefore a heat generation. Consequently, the adjacent relays was partly fused, and that was the smell, because the burned toroid was still heating the relay.
I think that this problem, using a 100watt rig like Icom IC718, on an AT Tuner that should stand 200watts, should not happen.
Anyhow, I asked LDG the service manual to repair the tuner, and LDG (Dwayne Kincaid of LDG Electronics Inc) replyed me that:
Hello,
We do not have a service manual for the tuner.
Dwayne Kincaid

So I asked at least a schematic diagram of the tuner, and:
Schematics are not available.

was the answer!
Astonishing, after sales service inexistent, same quality as the tuner, claimed to be built for 200watts max power and burned by 100watts, even for 15minutes continuosly.
Do you think that I'll recommend the tuner for quality and company service?

I have a YT-450 which I use with my FT-950. I have not left my rig on but I have had a similar problem.
Same reply from LDG too.
I don't understand why they won't let us have the circuit etc. All other reputable manufacturers will or do supply the circuit. Maybe they just want to make more money with the repair business.
They told me to send my unit back to them. The costs involved in sending it back to the States is just not practical.
I have heard of others that have had these sorts of problems.
Looks to me as if their products need to be down rated.
None of my friends who use the internal ATU in their rigs have had problems and that includes Kenwood, Icom and Yaesu.

Don't think I will buy LDG again, might be better to go for one of the Icom marine ATUs which you can pick up at every reasonable price on eBay from time to time.

I plan on doing the same, except two antenna options are enough.
Can [would you want to] put up a multi-band antenna, which is what I have now.

I should have two multi-band ants which should cover all I need.
Is it possible to switch antennas remotely using the LDG AT-1000 Proll ?
If so how?

Thanks
James

I would like to have the option of having he more antenna's available. That's why I'd like the RCS-10L. It's got 8 antenna connections. It's probably over kill but it's only $20 more then the RCS-4L that gives 4 connections. Mind as well get 8. :)

I just experienced the same thing from LDG last week.

A couple weeks ago I bought an IC-706 and an older LDG RT-11. It took me a couple days to try out my new purchase. It was "all" to be in working condx.

Well when I hooked it all up I discovered the tuner was not working correctly. So I opened the box (tunner case) and noticed right off that a cap was fried.

So, I called LDG and they identified the value of the cap for me. Since the cap was fried I expected other parts nearby to be damage as well.

When I called them up (actually all correspondence was via emails) they offered to send me a new cap and any other parts that may be needed. I then asked them for a schematic.

At that point they ask me why I needed a schematic? (duh!) The answer also was - no.

What it is, is LDG schematics are proprietary documents. In other words they won't give out schematics period !

After that, all I could do was to probe around to check a few other parts but couldn't locate any other defective components or burnt traces.

Since I did not have, or could not find a cap locally, I decided to use the closest rated cap that I had in the parts box. I installed it but still no glory.

In reading one of the email replies from LDG they told me that I could send it in to them and that there would be no charges for an evaluation (that was good news) and they would let me know of my options forthcoming.

I was reluctant to send it to them, simply because I contemplated whether or not the juice would be worth the squeeze. ($$$)

So now, I'm awaiting for a response from them. At that time I'll make the decision as to to write the tuner off or simply buy another tuner.

As for you looking for a specific tuner, model etc; Do your research on the particular tuner(s) that you have in mind. You can find out by reading the reviews of any said tuner. Then, determine what Product & Manufacturer to Order from.

Just Google the product you are interested, Look for Eham.net reviews.

Eham.net is your friend..... look up your "interest" and read the reviews of

any said tuner. It may sway you one way or the other.
Good luck,

Roger / KI8DU in WV

Sadly this has always been thier attitude. In fact their first tunner they refused to supply source code even though it was a lead article in QST. It was enough of an issue to me that I dropped my subscription to QST at that time and have never subscribed again. And sure enough there were issues with the code and revisions were issued. I assume we veryone had to pay for the newer code. The schematic was shown in the qst article and is basically unchanged in all latter units that I have looked at. Only component values and processors seem to change.

Hello All,

This thread stops now as it's degraded to misinformation and intentional incorrect information.

First, we supplied schematics for all the units that we provided as kits. After that, the units became less user serviceable because of surface mount parts and we still have not found the need to include them. If a toroid is damaged, you can “look” at the toroid and figure out the size and the number of windings on it. If a relay is bad, the part number it printed on the top of the relay. If the relay is smoked, the part number is still on the next relay over. If all that fails, you can e-mail us and we will tell you what it is. As we continue to use smaller and smaller surface mount parts, it’s becoming increasingly difficult for the user to service the unit.

Second, what only one person has mentioned is the fact that we will help anyone by e-mail with any question that they may have with identifying any part in any circuit. In addition, we will assist in troubleshooting any circuit that the customer may feel has an issue. Since nearly all of our products are microprocessor controlled, it’s is very difficult for the user to ascertain what a particular circuit is doing without knowing what the processor is doing so troubleshooting to a particular part is very limited.

Roger is banned for posting intentionally posting incorrect information. We told him what the part was, but he put in an incorrect part in and it still didn’t work. He failed to mention we offered to send him the correct replacement part at no charge.

Attillo is also banned for intentionally failing to mention that we offered to assist him in identifying any parts that he felt needed to be replaced. He quoted every e-mail except the one where the answers were offered.

Gary Foster is put on moderated for incorrectly implying that there were issues with the original code and a fee was charged for new revisions. For that model, there were no issues and we provided a free service to reprogram any processor as we added new features.

Roley is also put on moderated as he incorrectly implied that we wanted to make more money in the repair business. Our repair service has one of the lowest (if not the lowest) rates in the industry. You can send any product back to us at any time and we will check it out at no charge. If you feel the quote is too high, we will send it back to you at no charge and pay the shipping.

This is a group to discuss LDG products by LDG product users. Normally, our excellent group users will keep the order and no intervention is necessary. Unfortunately, this quickly spiraled out of control and steps needed to be taken.

We don’t mind seeing comments good or bad in this group. If you think a product sucks, tell the group why. However, don’t make up stuff and don’t lie.

It is a shame that these steps have to be taken. I have always had great service from LDG customer support. When I thought I had a problem with an out of warranty item LDG checked the unit out and sent it back to me at no charge. In addition, they were kind enough to let me know what my error was.
I would recommend their products anytime and am considering their new remote tuner.

Thanks,
David

On at least three occasions I had questions about a tuner and needed help. Not only did I get that help from Dwayne he also spent two days exchanging emails back and forth on a non-tuner related station problem. Nothing at all to do with the tuner - so there was no obligation to help. But he did. The help was volunteered, not requested. That is service way beyond I had any right to expect.

I am not a homer or a fan boy. I'm as cynical as the next person when that's needed. I'm sorry it took the note from Dwayne to bring me out of the weeds. But I have been well pleased with the products (I own two of the tuners) and extremely pleased with the service. I have no dog in the fight as far as schematics. But, from personal experience with the company, its products and service, I'm more than pleased.

I have an AT-100pro that I think isn't happy. I have used it in the past on 6M and done ok, but now whenever I unkey, it broadcast a buzz on the air. It last for about 3-5 seconds. Anyone had this happen?

If not, how is LDG repair as far as pricing goes?

I paid 50 bucks for it used 2 years ago and feel like I have my money's worth out of it.

I'm using a "Home Brew " fan dipole { laying on the three tab shingles on my roof,
a Yaesu FT857D,at times ,an AL 811A,and an LDG 1000Pro2 . 75/80 to six meters,
SSB AND JT65/JT9 ....from 10 watts up to 500 watts SSB,30 watts MAX on digital.
  Great tuner !! I started off with and LDG AT11,and as my power increased,so did the
power handling tuner . A friend recommended the LDG 1000PRO2 to me when I asked
for advice on an autotuner to handle the AL811A.   He put me on the right track,and
I am very happy with the LDG line of tuners .I also use the FTL meter !
  Great support as well,as I had to send a used LDG At 600 in for repair...about a
 week and a half turn-a-round , I recommend the LDG line of tuners to everyone that ask's.

I have 3 LDG tuners and have had great luck with all of them. I must admit I don’t do anything too strange or complicated and I try to adjust and cut to get the best possible match before committing it to the tuner for help.

The only issue I have is that they have made me lazy since they work so well. They tune stuff that probably shouldn’t be tuned.

I have a Z-11ProII and a AT-1000ProII and both work nicely. I did have a self inflicted issue once where I was calling CQ on a popular part of 40 meters and didn't hear anything. It turns out that I had the antenna coax physically disconnected from the tuner. The AT-1000ProII was absorbing all of the 100 watts from my transmitter and showing a good match on the meter, so watch out regardless which model you are using! Thankfully no harm was done.

Subject: RE: [LDG-auto-tuners] LDG AT-200 PRO11 AUTOTUNER

I have 3 LDG tuners and have had great luck with all of them. I must admit I don't do anything too strange or complicated and I try to adjust and cut to get the best possible match before committing it to the tuner for help.

The only issue I have is that they have made me lazy since they work so well. They tune stuff that probably shouldn't be tuned.

I need to add a positive prospective to this discussion.

I purchased a factory rebuilt AT-1000PRO from Cheap Ham. After a short time I had a smoking problem and as I could ID the fried bits, I contacted Dwayne who immediately sent me good parts. After replacing the parts, the problem re-occurred and I again contacted Dwayne who immediately offered to replace the unit with a shinny new AT-1000PROII which has been working flawlessly for the last year. It cost me 2 way shipping but well worth it.

Needless to say, I'm more than happy with LDG's products and service.

From: David Overton
Topic: 6778 Message: 6778

FYI All,

I have a RT-100 remote tuner controlled by a RC-100 to tune a S9v43. All LDG products. I had a problem when the tuner started stopping on high SWR - not low. After trying a number of variables trying to correct this, posting on here and email exchanges with Dewayne, I sent the tuner in for repairs. When it returned, No Joy! I then tried posting on here, again with no luck. And then, I sent it in a second time with the controller and power supply. Just got it back yesterday and this time it works. Persistence pays off; but, my hat is off to LDG for the great service after the sale.

Thanks You LDG and Dewayne,

David

6779. 44 foot CF Zepp issues

Happy for any thoughts on the following before I try to pull out a Smith chart for the first time in 20 years.....

I have trouble with my 44 ft CF zepp with about 100 ft of 450 ohm ladder line and the AT100 Pro2 - on 10 and 12, it hunts like crazy, and tho eventually settles in, remains unhappy with the slightest change in frequency, and it won't tune at all on 12.

Tonight I stuck a simple analyzer on the system to look at what the tuners sees - which is at the unbalanced input of the 4:1 balun suggested for open wire line, an SWR is around 8-9:1 on 10 and 12, and >10 on 15 >350 ohms as indicated on the analyzer), so I'm not surprised at the tuner being unhappy. 20 tunes fine at 6:1 and 17 great at 2.5:1. 40 even tunes well even though I have an indicated >10 SWR per the analyzer.

What I'd like to know is what to try next - whether it might be a good idea to change to a 1:1 balun, change feedline length, or whether I might have RF in the tuner, which is remotely located from the shack. Everything is pretty much balanced and grounded and has clamp-on toroids at the appropriate spots to fix common mode issues (I think).

Thanks for any thoughts.

Scott--
I had a similar problem, **MODELING ONLY** with an OCF 40M dipole. For education purposes, I scanned the antenna from 7 mHz to 30 mHz, and found surprising anomalies on 10M.
I then used the ARRL Transmission Line Program, TLW3. and found that the characteristics were Very sensitive to the length of the Ladder Line.
This line IS low loss, but it can act as a transformer, or a trap. You might try TLW, and vary the feeder length to see. Doing it for real should also be easy, by splicing in extra length, as a test. On high HF frequencies, 1/4 wave multiples are everywhere on long lines.

Bill your right today's software programs take the dredgery out of miles of detailed calculations on paper. You must also understand the associated theory behind the program and the various interactions that occur..

There are certain length of transmission line to avoid.

I had replied also about using a high impedance balun from Jerry Sevicks Transmission Line Transformer Book.

Remember you can substitues resistive values on a test bench
for balun testing to appear like a antenna is attached.

A voltage ballun is only a step up /down transformer depending which way you insert it.

Not sure if the originator is wanting to specific frequency correct or use a broad brush band approach.

A question can result in 10000 answers if specific are not stated.

Do not try a 1:1 balun as it reflects the antenna impedance value back to the tuner at the high values you have indicated below.

Go back and read up on some basic antenna theory and see the impedance with frequency change curve. Remember your antenna is a complex load of r-l-c values.

todays analyzer just make measurement easier but everything goes back to basic theory

You need to wind a custom balun out of Jerry Sevick book Transmission Line Transformers for a high impedance load at the receiver end of the transmission line eg your balunced line(350 ohm).your input impedance value from your profile graph and is specific at that one frequency

Make sure you profile each band from band edge to band edge(or your area of interest)) so you know the exact impedance your tuner sees.Remember the baic XL formula where the impedance changes with frequency.

The Smith Chart will only be accurate at the specific frequencies you profile and will give you lump values you need to add at that frequency.

The tuner is only trying to give you a 50 ohm load that the transmitter is happy with by inserting the L-C values remember the xc value is the opposite of xl and leave you with only the r value of the antenna

Most hams forget that fixing the antenna is the only solution

Go look at the impedance input spec for your tuner and the ranges it can accept.

I can't seem to get this combination to work. I've been in contact with LDG and they say that they no longer have a FT-950 to check out the Menu Settings. I believe that the law requires that servicing a product extends to 7 years past the end-of-life.

Anyway:

Does the FT-950 get set to "itu" or "Etu" to work with the YT-450?

I am using the FT-950, HRD 6x, WSJT-X and get the internal tuner to work fine on my 40-20-10-6 OCF. I wish to use it on 15m, which means a tuner is needed.

Where am I going wrong?

Brian,

Yes, I am using the specific serial port settings and I am using an old style RS-232 port into my computer and between the FT-950 and YT-950.

I finally got it to work by trial and error.

Evidently, the "Etu/itu" setting in the FT-950 menu has no affect on the operation. Your opinion or experience?

What seems to matter is that the front panel "TUNE" button on the FT-950 must be off. This is not spelled out in the YT-450 Manual.

It would also have been very nice if the people at LDG had added 2 more LED's to the front of the unit - one indicating "inline" and the other indicating "straight through". So, that created some operator error, because you can't look at the unit and know what state it is in.

Brian,

TNX!

I also found out, by trial and error, that the Menu Selection for "Internal/External" (itu/Etu) on the FT-950 doesn't seem to make any difference one way or the other.

In all of this, I have discovered that I have a defective unit, after many e-mails back and forth with LDG.

I finally started asking questions in the form of "is this normal?" That apparently worked the best, because when I got technical, they couldn't answer the questions.

I am sorely disappointed in their tech support and the inadequate manual.

They also do not have a FT-950 anymore to check out problem solutions. I found that to be very un-customer friendly for those of us that bought the unit because the advertising states quite clearly that the unit works with the FT-450 and FT-950.

I am sure that I will be happy with the unit when I get it back (after I send it in), but right now I am very disappointed with customer support and the problematic unit.

Neil, K7IPP

PS Thanks for your feedback.

Bill - thanks, finally got a chance to add a bit of feedline this weekend, and the good and bands have changed a bit, so I guess I will try TLW and do a little modeling form the safety of the desk rather than the ladder and look for the majic length:) Appreciate the response, 73 Scott

In a message dated 5/21/2014 9:27:25 P.M. Central Daylight Time, LDG-auto-tuners@yahoogroups.com writes:

Scott--
I had a similar problem, **MODELING ONLY** with an OCF 40M dipole. For education purposes, I scanned the antenna from 7 mHz to 30 mHz, and found surprising anomalies on 10M.
I then used the ARRL Transmission Line Program, TLW3. and found that the characteristics were Very sensitive to the length of the Ladder Line.
This line IS low loss, but it can act as a transformer, or a trap. You might try TLW, and vary the feeder length to see. Doing it for real should also be easy, by splicing in extra length, as a test. On high HF frequencies, 1/4 wave multiples are everywhere on long lines.

Subject: [LDG-auto-tuners] 44 foot CF Zepp issues

Happy for any thoughts on the following before I try to pull out a Smith chart for the first time in 20 years.....

I have trouble with my 44 ft CF zepp with about 100 ft of 450 ohm ladder line and the AT100 Pro2 - on 10 and 12, it hunts like crazy, and tho eventually settles in, remains unhappy with the slightest change in frequency, and it won't tune at all on 12.

Tonight I stuck a simple analyzer on the system to look at what the tuners sees - which is at the unbalanced input of the 4:1 balun suggested for open wire line, an SWR is around 8-9:1 on 10 and 12, and >10 on 15 >350 ohms as indicated on the analyzer), so I'm not surprised at the tuner being unhappy. 20 tunes fine at 6:1 and 17 great at 2.5:1. 40 even tunes well even though I have an indicated >10 SWR per the analyzer.

What I'd like to know is what to try next - whether it might be a good idea to change to a 1:1 balun, change feedline length, or whether I might have RF in the tuner, which is remotely located from the shack. Everything is pretty much balanced and grounded and has clamp-on toroids at the appropriate spots to fix common mode issues (I think).

Thanks for any thoughts.

Evidently, the "Etu/itu" setting in the FT-950 menu has no affect on the operation. Your opinion or experience?

What seems to matter is that the front panel "TUNE" button on the FT-950 must be off. This is not spelled out in the YT-450 Manual.

It would also have been very nice if the people at LDG had added 2 more LED's to the front of the unit - one indicating "inline" and the other indicating "straight through". So, that created some operator error, because you can't look at the unit and know what state it is in.

My station consists of a Yaesu FT1000MP and Quadra amp. I'm confused between the semi automatic and automatic modes with an amplifier. The automatic mode tunes the tuner when RF is sensed but the semi automatic mode only tunes when the tuner tune button is pressed. LDG does not provide a cable for the Yaesu FT1000MP. The Quadra uses the the tune jack on the back of the FT1000MP to key it.
It appears that the Quadra must manually be put in standby after transmitting and then changing frequency, in the automatic mode, to prevent the tuner from retuning with the amp activated. Has anyone figured out how to wire the AT1000PROII so the tune button on the tuner in the semi automatic mode will work with this type of setup with the Quadra? Thanks for any suggestions.

There is circuitry in the tuner that bypasses the unit if you try to tune at over 150 watts. The manual suggests you tune at 20 to 50 watts and only apply full linear power once you’re tuned.

I use semi-auto to tune. I have a macro set up in Logger32 that sets my FT9000 to 30 watts and then turns on the TX at 5 khz above the current VFO frequency. A short press of the tune button on the tuner recalls (in most cases) a tuning solution. I also have a circuit that opens the PTT line (there is an output from the tuner that can be used for this) to the linear to prevent it from keying while tuning.

Gerry,

That is not correct. The tuner will do "nothing" with the relays if there is over 150 watts of RF. The issue here is if there were high RF and the relays went to bypass, then you would still arc the contacts when they released. So, the solution is to never change a relay when the RF is over 150 watts.

Dwayne,

Maybe I was less than clear. Also, I don’t have the text of my original comment on this machine.

I believe my problems with the original Pro I had and that you graciously replaces with the ProII had a malfunctioning hi power protection circuit which lead to it demise so I’m now overly protective.

I use the KEY line from the tuner to open a relay in the PPT line to the tuner to disable the linear if the tuner is searching for a solution or just going to a memorize solution.

What I am unclear about is what would have happened before I opened the PTT line if I’m in full auto-tune and I move to a new frequency or band with the linear on. Will the hi power protection circuit drop the tuner into bypass?

In any case, great tuner. I’m also using a borrowed AT-7000 on my IC-706 and It’s also great.

Hi Gerry,

If the RF power is over 150 watts, it will not drop the tuner into bypass. The tuner will do nothing but give an over power error message on the display (on the meter for the AT-1000Pro).

Yes, if the protection circuit failed in the LDG tuner, it may damage the tuner. Fortunately this rarely happens.

Even if the tuner was in full auto mode, if the RF power is over 150 watts, it will not change any relays, but give you the error indication for too much RF power for tuning.

Using the key line available on the back of the tuner to disable the amp while tuning is a great way to configure the amp. This almost guarantees that you will not have dangerous RF power when tuning. The interface application note that describes how to do this is available on our support page for those that are interested.

W6OGC here. I just received and put into service the RT-100 and RC-100. At the moment it is matching a home brew S9v31, which is also recently installed.

I cut the wire in the fiberglass pole long, at 33', not thinking of the ramifications for tuning in multiband use. When my analyzer showed some goofy looking readings, I loped off about a foot. The antenna at present has 3 Petowany coils 31' each at the base; a fourth is planned soon.

The tuner could not find a good match on 18.1 Mhz. or on a couple of other bands, >3:1. I have a feeling this has to do with the length of the wire which needs some adjusting. 20M was that way, too, when I tried it with the Icom 706. I would think that a match for a given antenna and feedline would be a good one no matter what transmitter was used. It finds a match using the Omni VI+ but not the Icom 706, very peculiar.

The Icom 706 has its own tuner control circuit. I have a device connected to this, in the absence of the Icom remote autotuner, that gives about 8 seconds tuning cycle. The RT-100 is unable to find a match in that time in many instances, and it starts over with each new cycle. I have to either connect a straight key or switch to AM mode and key the microphone to get a long enough tuning cycle.

I'm looking forward to addressing these anomalies and getting the tuner in full use. Suggestions gratefully received!

I have made improvements to my KT-100 mobile installation, and operation is better. The biggest change was to increase the length of the coax from the KT-100 to the antenna feedthrough on the roof to about three feet. This allowed me to increase the number of ferrite beads on the coax, making a current balun, to 11 (from 8 on the 2-foot coax and 3 on the 8-inch coax). These are mostly mix 31, but there are also a few of mix 43 and mix 77 beads. Mix 31 is recommended for HF, while mix 43 works better for VHF and mix 77 works better for MF. Lengthening the coax goes against the recommendations I have read for keeping any coax between the tuner and the antenna as short as possible. I think this works for the KT-100 because additional ferrite beads increase the isolation from antenna currents on the outside of the coax from causing RFI to the tuner. So, now the KT-100 tunes the SG-303 on 75m. Still not very efficient until I insert an 80m coil in the middle. I added a couple of 0.5" I.D. split ferrite beads to the fuel pump power lead, and that helped reduce noise from the fuel pump, so the mobile installation works pretty well 40-10m. Haven't done much more that listen on 75m, so I don't know how well it gets out on 75m.

6802. Recommended tuner for FT-102

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-06-08 11:47:16 UTC
From: Giuseppe Marullo
Topic: 6802 Message: 6802

Hello,
I have a FT-857D with a LDG ATA-100 Pro, and so far seems pretty good combination. I use it remotely and with a webcam I can double check everything is fine.

Now....I got a FT-102 and this has much greater punch than the 857.

I am keen to acquire a original FC-102 antenna tuner, but it is not cheap. Despite the wonderful look, the 1.2kW handling capability maybe a LDG tuner would be a wiser investment.

So my question is, is the ATA-600Pro II the only viable substitute?

Thanks in advance.

From: wb4rtp@...
Topic: 6802 Message: 6803

Giuseppe,
From the information I can find about the FT-102, it is a 200W transceiver, so an AT-600 would be a bit of overkill. However, the AT-100 would be a bit light unless you wanted to turn the drive down and let the finals loaf, but the AT-200 should be just right. But, if you just want a substitute for the FC-102, I think that was a manual tuner, so any of the many makes and models of manual tuners rated over 200W should work similarly to the FC-102 (some better than others, look for reviews such as those at eHam.net).

Hope this helps!

From: rolandbrade@...
Topic: 6804 Message: 6804

I now have my new AT-600 up and running and it works very well. Tunes my Butternut HF9V and my trap inverted L with no problem at all.
The only downer is that it is pretty noisy, but then this shouldn't matter too much as it is pretty quick with the tuning cycle.
In any case once you have been through all the bands/frequencies that you use the memory remembers the positions so it is spot on when you come back to a band/frequency. I use JT65 a lot and it remembers the tuning for each band/JT65 frequency.
The other nice feature is that you can manually change the L/C settings if you want to give a final tweak.

From: john.brent@...
Topic: 6805 Message: 6805

Im having an issue with my assumptions as to how this tuner works. I have a Z-11 ProII as well as an IT-100. With the Z-11 It would sense what freq I was on, and tune. If it was not a memory It would go threw he tuning process. All I had to do was key up on the mic. With my IT-100, It does not seem to work that way at all. I seem to have to press the tuner/call button every time I change the freq. Is there no auto tuning, it says there are memories, but it always seems to go threw the tuning process as if it was a brand new freq.

Thank you,

John Brent

From: rds@...
Topic: 6806 Message: 6806

"Just key and it tunes! The AT-1000ProII will operate at any power level between 5 and 1,000 watts peak RF input."

This is a sentence out of the LDG website - I'm not sure whether this correct.

I own a very special and very excellent SDR radio (Reuter RDR 54D from a small German company) with 5 watts, max. 6 watts output. With this 5 or 6 watts and the PA at bypass the tuner will not tune.

If the PA is active I will have around 100 watts at 5 watts output or any combination between 1 and 5 watts output with less output at the PA - so enough power for tuning, so normally no problem.

The problem is, that the PA stops working if the SWR will be larger than 1:3 to prevent the PA. That's the dilemma.

5 to 6 watts are not enough output for tuning, if the SWR is > 3 the PA stops.

Is there any chance to adjust the input level of the AT-1000proII that this unit will auto tune at 5 watts as it is described in the advertising ?

Thanks for any comments.

Topic: 6807 Message: 6807

Hi,

have a FT 857D in my car - head beside the dirver seat black box at the end of the car. Sometimes it would be helpful to have a tuner in ther car and so I thought to buy a YT-100.

Before that I have read in the manual that for a tuning cycle I have to press the tuning buttom at the YT-100 which is fine when the tuner stands beside the radio but not here in the car as described above.

My question now, it is possible to start a tuning cycle with the YT-100 at the FT-857D like with the original Yaesu FC-30 and the respective menue stettings or not ? Or ist there another tuner available from LDG where I can do this (AT-100proII or so) ?

Otherwise I must order the FC-30.

Thanks for your assistance.

Don’t forget that the FT-857 has an accessory jack on the rear where you can configure a push button to place the radio in the transmit mode sending a CW carrier for tuning. It would require another cable run from the rear of the car to the front but would give you additional flexibility in choosing a tuner.

John,
The IT-100 is "optimized" for use with Icom radios, but I think it is similar to the KT-100 I have that is intended for use with Kenwood radios. Both of these emulate the autotuner built by the radio manufacturer for use with their radios, so they are limited to what the OEM autotuners could do. For instance, the KT-100 will tune on 6-meters, but since the Kenwood autotuner it replaces could not do so, the Kenwood radio won't allow external tuner operation on 6-meters (it works fine if I manually transmit and press the KT-100 front panel tune button). So, as to your question, yes, you have to press the autotune button on the radio for every new frequency because that is how the radio manufacturer's autotuner worked, and that is how the radio is programmed to expect an external autotuner to work. But, at least the button on the front panel of the radio is convenient.

The KT-100 does have memories. If I return to a frequency I have previously tuned and press the autotune button, the KT-100 will click once (all the relays going to the previously memorized positions), the radio meter shows low SWR, and it is done. If the antenna has changed, the meter shows high SWR, and the KT-100 goes into its autotune sequence with the attendant relay noise.

Now, here is a tip I learned from using the KT-100, which may be applicable to the IT-100. Several commenters have warned that the LDG autotuners are sensitive to RFI. I have seen this in the KT-100, so I now have large ferrite supressors for all three cables connected to the KT-100, input and output coax, and power/control. These act as current-mode baluns. This is in my mobile installation, and you can see pictures in the photo area of this forum.

Rolf,
I hope my experience with the KT-100 and a Kenwood radio in a mobile installation will be helpful to you. Like you, the KT-100 is installed in the back near the antenna so it is not accessible from the driver's seat where the radio control head is. Instead, there is a multiconductor cable that connects the KT-100 to the radio and supplies power and control signals. With this cable, the Kenwood radio operates as if a Kenwood external autotuner is installed so that the autotuner button on the front panel of the radio activates the KT-100. This was all explained in the manual for the KT-100, so I would hope that the manual for the YT-100 would have a similar explanation. You can see photos of my mobile installation in the photo section of this forum.

6813. Z11 Pro II Fine One Day, Won't Tune At All the Next?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-06-13 10:46:58 UTC
From: kirk@...
Topic: 6813 Message: 6813

Hi, gang,

On the eve of the VHF QSO Party, my Z11 Pro II is being weird...

A week ago I replaced an SGC autocoupler that needs TLC with my Z11 Pro II. It's in my attic, and it feeds a 40-meter horizontal loop via a 20-foot length of 600-ohm open-wire line (not ladder line) from 80-6 (not much 80). I set the auto-tune threshold to 2.0 and used it on every band for a week. I never run more than 5-10 W (KX3).

I'm sure there are a few odd impedances in there, as 10 MHz tunes "slowly," but everything was working FB for the duration.

Tonight, however, it simply won't tune at all. On two bands it has a 2.3:1 SWR (okay), but when I send RF on other bands, it doesn't make any attempt to tune.

I power-cycled it, which I can do without accessing the attic hatch, but there was no difference.

Obviously, I need to "blow the hatch" and have a look-see, measure the dc voltage at the jack, force the tuner to do a few manual/full tunes, etc.

But I'm wondering if there's something obvious that I'm missing?

Last week I swept the loop (where the open-wire line connects to the tuner output) with my MiniVNA to see whether a 4:1 balun at the tuner output (between the tuner and the open-wire line) might generally provide better impedances, but I haven't had time to review the numbers, I merely saved the sweep data for later analysis. I can't access the actual feed point, which is on the outside wall of the attic, "many" feet away from the hatch. :) So I had to sweep with the open-wire line attached. I doubt there's an open or short, as an ohmmeter check for end-to-end continuity was normal.

This thing works *really well* for an indoor antenna, but I have been having recurring "goofy" issues with my autotuners for the past few years. The SGC is 15 years old and has seen many an outdoor MN winter, so I have no doubt that it needs relays and/or diodes and/or counter chips, but the Z11 has never been outside and has been treated well since day one.

Thoughts? Help?

As always, I appreciate your insights,

--Kirk, NT0Z

6814. S9 Antennas Discontinued

While we have plenty of stock of S9 antennas, we've come to the decision to suspend any future production of more S9 antenna units.

The antennas that we have in stock will be available through www.cheapham.com http://www.cheapham.com until the supply is extinguished. They will have an aggressive price structure that will move the remaining antennas at a very rapid pace.

Don't miss out on the discontinued price. These antennas have been successfully proven as good performers for nearly a decade from the original owner, then through LDG.

Mike,

I live in MN, but attics can still get hot here. Mine sure does.

I opened the hatch to check on the tuner and the exterior case was 120 F according to my non-contact infrared thermometer.

I noticed that the two most right-hand leds were lit, so I power-cycled the box (15V dc measured) and switched it between bypass and tune (just once), and it started working fine (has been all day).

I KNOW the tuner locks up when it's below zero, but I didn't think warm WX (hot attic) would make it fritzy.

I may have to figure out a way to bring a piece of open wire line through the sheetrock ceiling or the wooden attic hatch so I can keep the tuner in the climate-controlled part of the house (by six inches or so).

Last winter I moved the tuner to an upstairs bedroom, just beneath the attic and the loop, and the antenna worked horribly, even with only a 25-foot run of RG-6 between the tuner and the coax/open-wire line transition. It tuned and loaded perfectly, but the antenna went from fantastic to poor in one fell swoop.

Last evening I put 10 new "entities" in the log on 18 and 24 MHz just by answering random, non-contest CQs while running 5 W on CW and SSB (the 6-meter QSO Party was DEAD all day). In its present configuration -- tuner in the attic, loop fed with 20-feet of open-wire line, right to the tuner output, and a 50-60 foot run of RG-6 from the shack to the tuner (choke balun at tuner input and on dc leads) it works great...but if I add a run of coax from the tuner output it becomes a fancy dummy load :)

Maybe I'll have to cool it with thermoelectrics, a Peltier cooler, etc :)

Thanks,

Well, yes. The 25' of RG-6 has huge losses at high SWR. Sure it loads up nice, but all the power is going away before it reaches the open wire line.

LDG suggests using a balun after the tuner, and specifically mentions keeping the coax between the tuner output and the balun short. Preferably under 3'.

At a minimum, I would suggest a 1:1 current balun to properly transition from the UHF connector on the tuner to the open wire line. Personally, I use a 9:1 current balun to feed the 450 ohm ladder line going to my doublet antenna. The coax I use to connect from the balun to the tuner is RG-213, and it's only about 24" long.

Both MFJ and LDG sell a 4:1 current balun. DX Engineering sells a 9:1 as well.

Topic: 6813 Message: 6818

Jeff,

Yes, I have been considering the 4:1 current balun. I can mount it directly to the UHF connector, no coax required.

I have used my autotuners with directly fed open-wire line (without the balun) for 15+ years...and they work so well...that I'm reluctant to add anything that might decrease performance :) With a closed loop, as opposed to a doublet, I'm not so sure that electrical balance on the open-wire feeders is really necessary.

I swept the loop with a VNA (at the end of the open-wire line). I will post my impedances in the next day or so (once I extract them from my "war zone" laptop) to see if the balun -- or even a lump-sum L or C -- might tame things a bit.

I have 8 pairs of 22-gauge wire running between the shack and the attic tuner, so I could mount a relay or two if it looks as if that might be useful.

Thanks again,

Date: 2014-06-14 23:14:03 UTC
From: cdruhl@...
Topic: 6820 Message: 6820

Hello group!

I'm a new, happy owner of a AT-897 Plus which has made life easier with the FT0897. I am using a doublet dipole of random size. I can tune pretty much any band for good match but have some quirks with 20 meters.

I attempt a tune on 20M and get back what looks like three flashes on the LED, which in the manual says a match of SWR above 3:1. I get this most of the time. Curious as to how close the match was to 3:1, with one such "three flash" situation on an unused frequency, I dropped the FT-897's power down to 5W, set mode to Phone, and keyed up to find a low match on rig's SWR meter, no power fold back. I increased this up to 90W slowly and got no worse than a 2:1 and never did the HSWR indication arise, though nobody came back to my call. I'm trying to figure out what I'm not seeing or understanding . . .

Very nice tuner, would be hard to go back to manual tuner for what I'm doing here . . .

I attempted to work 60 Meters today and notice that the FT-897 and the AT-897 Plus will not communicate when attempting a match on 60 meters, failed tune every time. My multiband antenna has a base SWR of about 5:1 so it should match it, but then I remembered reading in the manual that the tuner automatically puts the FT-897 into AM mode to do its tune magic. We're only allowed SSB and CW on that shared band in USA, and the FT-897 only lets me select SSB or CW, and so I'm guessing FT-897 rejects the command and the AT-897 flashes either a four or five error code to indicate a failed tune cycle.

Is there a workaround for this or am I doing something wrong? I see no reference in the manual to this issue.

Thanks!

Topic: 6821 Message: 6822

Try tuning in cw at 10 watts.

Also reduce your swr 5:1 is a horrible match.

Might have been ok with tube rigs but solid state rigs fold back at 2:1.

You need lots of realestate for a antenna in the khz range that 60m is.

The tuner spec say for its input impedance range 6 ohms to 800 ohms

Do you know what your antenna impedance is, what kind of antenna are you using?

Its easier to fix the antenna than blowup your expensive rig

Subject: [LDG-auto-tuners] AT-897 Plus and 60 Meters

I attempted to work 60 Meters today and notice that the FT-897 and the AT-897 Plus will not communicate when attempting a match on 60 meters, failed tune every time. My multiband antenna has a base SWR of about 5:1 so it should match it, but then I remembered reading in the manual that the tuner automatically puts the FT-897 into AM mode to do its tune magic. We're only allowed SSB and CW on that shared band in USA, and the FT-897 only lets me select SSB or CW, and so I'm guessing FT-897 rejects the command and the AT-897 flashes either a four or five error code to indicate a failed tune cycle.

Is there a workaround for this or am I doing something wrong? I see no reference in the manual to this issue.

Thanks!

60M isn't resonant with anything else, so I am not surprised it doesn't work.

Regardless of what mode the radio is in, that has nothing to do with the tuning of the antenna.

In order to help you out, we will need to know what you are using for an antenna.

Just because you can get a tuner to tune an antenna, doesn't mean that it will radiate a signal. You might be just turning all that RF energy into heat and that isn't what you want.

Unfortunately good SWR only means the radio is happy. Bad SWR means the radio isn't happy. Still, I'm not surprised you are having issues.

6825. RE: [LDG-auto-tuners] AT-897 Plus and 60 Meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-06-16 22:25:35 UTC
From: Chris Ruhl
Topic: 6821 Message: 6825

I shared one solution in a different note - since the AT-897 Plus puts FT-897 into SSB mode automatically, I can't tell the AT-897 tuner to use CW for a tune cycle, I drop power to 5W, initiate a tune, key up microphone, and sign with call while the tuner is doing its tune cycle. Works like a charm.

The AT-897 does take care of the 5:1 match; in fact it got it down to 1.5 to 1 - I wasn't attempting to use my doublet dipole fed with ladder line and balun with coax to station without a tuner, I got it to tune by accident and then couldn't get it to do it again - I had enough local noise to set off the tune sequence the first time. My antenna is small but okay for NVIS work.

I only went through this exercise on 60M because a radio friend 60 miles away wanted to work me on 60M, which we did. I can get my small antenna to tune on 80M for CW work and enjoy working guys with straight key in a 500 mile range when band conditions are good.

Thanks, all, for the replies

Subject: Re: [LDG-auto-tuners] AT-897 Plus and 60 Meters

Try tuning in cw at 10 watts.

Also reduce your swr 5:1 is a horrible match.

Might have been ok with tube rigs but solid state rigs fold back at 2:1.

You need lots of realestate for a antenna in the khz range that 60m is.

The tuner spec say for its input impedance range 6 ohms to 800 ohms

Do you know what your antenna impedance is, what kind of antenna are you using?

Its easier to fix the antenna than blowup your expensive rig

Yes, you are correct, and that much I knew - but the AT-897 can't be programmed to put the FT-897 into CW mode during a tune cycle -- at least I know of no way - perhaps it would be nice if the AT-897 could bet set to go into CW mode for 60M only and send a carrier.

I finally discovered a solution with the help of LDG support and the bit in the manual about anything spoken into the mic is transmitted during a tune cycle: The AT-897 puts the FT-897 into SSB mode on a 60 meter tune cycle, and any audio into the microphone will cause a carrier - so I set power low to be safe, find an empty 60 meter channel, press tune button as normal to initiate a tune cycle, press the mic's PTT, then say my call sign and "testing" or "tuning" into the mic to generate a carrier until the tune cycle is complete and stored into memory, which doesn't take long. That setting will hold me for the other channels and it should take no time now that the memories have it, at least for now.

This is my first shot at auto-tuners and 60M in same boat, been using manual tuners for past 25 years, all new! I wish I had gone the auto-tune route sooner!

6827. RE: [LDG-auto-tuners] AT-897 Plus and 60 Meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-06-17 01:25:51 UTC
From: Chris Ruhl
Topic: 6821 Message: 6827

I suspect that I caused confusion by incorrectly formulating my question, my fault. I have an LDG AT-897 and a Yaesu FT-897, a custom match. AT-897 manual points out that the tuner works by the CAT cable connection between tuner and radio. The LDG tuner reads the frequency from the radio, then sets the radio to low power, AM mode, and seeks a match - and the tuning range is very good, much better than the stock Yaesu FC-30. My whole issue was trying to get the radio-tuner combination to do a successful tune on 60M. I was able to follow the instructions in the manual (I did read it cover to cover before working the LDG tuner) but on 60M I got "no RF" or "Lost RF" error messages. I finally learned to tune on 60M by initiating a tune on the AT-897, which puts my FT-897 into low power in SSB mode, and then speak my callsign into the mic repeatedly - which puts a carrier into the tuner -- while it found its match and put all in memory. This gave me a very low match. I just tried to make absolutely sure within reason that nobody was using the frequency (channel, actually) so as to not tune on top of a QSO, and I kept power low.

My apologies, please, for clogging up the board with this. I do thank everybody for trying to help and all is fine now. I always used multi-band antennas of random length from limited space and use ladder line with balun and coax for a feed line and minimized QRM by tuning off-frequency with low power or, better yet, using my MFJ-259B analyzer to get my match with the manual tuner and check my antenna before turning on the radio. I used to keep a chart of match configurations for the two caps and roller inductor for each band or portions thereof, next to the tuner, to make it easier. The procedure for doing an auto tune on 60M seemed to go against all of what I learned early on as a Novice - don't stomp on the other fellow's QSO, tune only on quiet portions of the band, ask if the frequency is in use. This is my first crack at an ATU, ever. I wish I had made the move sooner!! I now spend more time working stations than time off-air changing bands and other adjustments (which was really time consuming when I was using my old boat anchor tube rigs as the tuning process with those rigs can or will conflict with a manual tuner, like two tuners in series, and I could run with a high SWR at times and still have effective contacts. Using compact antennas as I do usually means narrow bandwidth - or sometimes too much which is usually no good!

I was making contacts and using my new LDG tuner just fine - I have a doublet dipole which is more or less the right size for 40M -- my antenna analyzer gives a very low SWR curve in that band with very close to 50 ohms of resistance. My problem happened when I telephoned a friend who lives 60 miles away from me to for a sked to have some HF fun on 40M which we did for a while and then he suggested that we try a channel on 60M for grins as there was no activity over there and I've never had a radio which could do 60M until I acquired the FT-897 a month or so ago. The LDG AT-897 tuner

would not tune on 60M - because the tuner wants to put the radio into AM mode which is locked out by the radio for 60M - the radio only allows SSB or CW and I can't modify the LDG AT-897 to change it to CW for a carrier. I had only been using the tuner for a few hours and had no problems at all until trying to tune up on 60M while on the phone with the other operator - I did get the tuner to work by accident because the microphone was picking up ambient noise but I was getting a message from the tuner (three flashes of the LED after the tune cycle was over) that my match was over 3:1, which didn't make much sense. We had a nice QSO on 60M, I was on 50W, which lasted about fifteen minutes (he copied me 55 to 57) - the FT-897 read an SWR of about 2.5 to 1 - the FT-897's "High SWR" warning never came on.

I took my antenna analyzer and plugged my antenna coax right into it, no tuner, no rig in the loop, and read 5 to 1 SWR because, initially, the tuner was giving the high match apparently because it wasn't getting a good carrier at the time and the process ended prematurely - I forget the exact impedance values but I know the radiation resistance wasn't good, the impedance was too high, efficiency was lousy and my low signal was thus of no surprise and to be expected - so one of my next projects is to home-brew an antenna just for 60M. All of my antennas are compact, compromise home-brews because of severe space restrictions which I cannot control.

So, we're good - and thanks again. Good DX to all! 73 DE N3GBJ

Subject: Re: [LDG-auto-tuners] AT-897 Plus and 60 Meters

What do you mean your base swr is 5:1?

60M isn't resonant with anything else, so I am not surprised it doesn't work.

Regardless of what mode the radio is in, that has nothing to do with the tuning of the antenna.

In order to help you out, we will need to know what you are using for an antenna.

Just because you can get a tuner to tune an antenna, doesn't mean that it will radiate a signal. You might be just turning all that RF energy into heat and that isn't what you want.

Unfortunately good SWR only means the radio is happy. Bad SWR means the radio isn't happy. Still, I'm not surprised you are having issues.

If you were to do the wideband mod to the radio it should let you tx anywhere on HF in any mode. The mod does remove the auto repeater shift, not sure what it does to the 60m channels but like your repeaters, the channels could be programmed into normal memories anyway.

My station:
IC-718
LDG Z-100Plus tuner

W8AMZ 80-6M ocf dipole

When rf output is around 30-40 watts I can hear a relay cycling on the tuner. My radio is configured to only tune when pressing the Tune button. I've tried placing ferrite beads on the tuner power and control leads. I've also placed beads near the the feedpoint of the antenna in addition to the balun that I wound near the feedpoint. I also sent in the tuner but they couldn't find anything wrong with it.

It's cycling when it's not in a tune cycle. Not an issue on digi modes as I run 15 watts max on those modes but it's very much noticeable on phone.

Okay. I checked the user manual for that model and unfortunately it does not have the feature some of the more advanced tuners have, which is the ability to turn off automatic tuning or adjust the SWR threshold for automatic tuning.

What I would suggest is to wire a switch into the DC power lead and after it tunes, turn it off. It uses latching relays so it will remain at the last tune setting, and this will solve your problem.

I just extended the original 14" cable of my IT-100 (connnected to an Icom IC-7200) by about a foot, using #18 stranded hookup wires and did a pretty good job soldering the wires and put heat shrinks on the joints.

I think my original SWR readings of about 1:1.4 on several favorite freqs now are about 1:1.7. I observed this after did a full tune on my favorite freqs.

Could my extending the cable could have caused this? Does this mean a need for recalibration of the IT-100?

Is the "cable" between the two coax, carrying RF? If so, using hook up
wire is a bad idea. No telling what the load looks like going through that.

Use 50 ohm coax between the two.

Ramon, if I understand correctly, you extended the control cable between the tuner and your rig, correct? If this is the case, I would think this should have a minimal to no effect on your SWR. In fact, it appears your measured SWR is still under 1:2. A difference of 3 tenths of a point is negligible. I, personally, don't think you have anything to worry about.

I'm guessing by extending the control wire you moved the unit. See if you have wires that touch crossing at angles. 1.7 is a good SWR. Not a big deal, really.

Sorry I assumed all LDG atu had this cable, yes its a control cable that goes between the radio ang the IT-100 not the coaxes. I agree that 1.7 swr is not too bad, its just that if I closely observe my forward power output, it seems to go down slightly, eg, 10W to 9W over 50 sec keyed on JT65, (this could be another issue). Tks

Some meters don't read perfectly linear so often there is a change of SWR reading at higher power and I've also seen that lower power will often show lower SWR in a bariety of meters. Like the others have recommended, try not to worry about it. Via an online calculator, 1.7:1 is a 6.7% power loss and 1.5:1 is a 4.0% power loss. Not a big difference.

Another way to look at it, from the same calculator, 1.7:1 is a 0.3 dB loss. If an S unit is considered to be 6dB, that is 1/20th of an S unit :-)

Ramon,
When I first tried to extend the control cable for my KT-100, it didn't work. I had two issues to address before I got it working:

1. Signal integrity: The KT-100 has two control signals plus power and "ground", which is the return for both power and signal. I used CAT-5 cable which has 8 conductors in four twisted pairs. Each pair consists of a solid color insulation and a striped insulation, i.e., green paired with green-white. I connected all of the striped wires to ground. Two of the remaining solid color wires went to power, and the remaining two wires each went to a control signal. This makes sure the twisted wire pairs are properly utilized. I used the diagram in the manual to make sure I had the wires hooked up correctly since the connectors are different at each end. This method gave me proper wire pairing for the control signals which are normal logic levels and can easily be corrupted with ground-loop noise.

2. RFI: Once I had a good control cable, I added a ferrite suppressor to choke RF currents. Specifically, I used an FT-240-31 toroid core, and wound 8 turns of the CAT-5 cable on it. You could use split bead ferrites, but you should install several. Since I have read accounts, and experienced for myself, RFI in LDG tuners, I also installed ferrite beads on the input and output RF coax, which amounts to current baluns. This may be overkill, but it works for me.

Hello,

You can download both manuals from the Yaesu web site and look at the CAT commands. You'll find that they are not compatible.

Typically, Yaesu CAT commands go in pairs of radios. FT-857 and F-897, FT-450 and 950, FTDX1200 and 3000, FTDX-5000 and 9000. Then there are singles that are only compatible with themselves: FT-817, FT-100, FT-847, FT-2000.

I may have missed a couple, but you get the picture.

Hi Avery,

I much appreciate your followup on my post. I think its a very good idea to use the Cat-5 cable and using a lot of ferrite beads.

The original LDG cable was foil shielded with a bare ground wire in it and so was concerned about the exposed portion of my hookup wires (#18) extension. Very crude but what I did was wrapped my extension with a couple of layers of aluminum foil, overlapping the ground wire, and wrapped the length with electric tape, paying particular attention so that the end that overlaps is tight and put a couple of small cable ties in this area. There was some improvement on my SWR, but still not the same as before, so I might try your advise one weekend.

Thanks & 73,
Ramon VE7RVS

Hi Ramon

That is propperly the answer to your question.

You changed some thing in the set up and reconnected it all.

When you reconnect ths "chance" of doing it 100% the same way are 50/50 unless you use a torque wrench.
Also bending coax cables changes things.

And...

If the transmission line is not fully "decoupled" from the antenna, or the transmission line is in the near-field of the antenna and there's no effort to limit coupling into the outer shield of the transmission line, the line and anything connected to it becomes to some extent a part of the antenna. If that's the case and there's changes to things connected to the transmission line, even power connections to a tuner, those changes will unavoidably have some effect on the antenna "system" behavior, including possibly slight (or perhaps worse) changes in SWR.

Do you know where your antenna is? Or more correctly, what your antenna is?

From: allister_mclane@...
Topic: 6852 Message: 6852

Hi,

maybe a stupid question.

Can I use the Kenwood TS-480SAT with the AT-1000 Pro II ?
I didn't find any cable for the radio to the tuner (like ICOM or YAESU). Is there no cable available for Kenwood ?

This would mean that I have to start a tuning cycle by pressing the Tune-buttom at the tuner or due to an over-SWR condition situation. Am I right or is there a mistake in my thinking ?

Many thanks for your assistance.

Rolf DO1ZZ

Many thanks Stefan. To make it easy for me. Does your interface work like the cable for example between ICOM IC7000 and AT1000proII,
means pressing the tune buttom at the radio and the tuner starts with tuning ?

Rolf,
If you want to use the tune button on the radio control panel, I would recommend the LDG model KT-100. I use a KT-100 with my TS-480SAT and it works great in my mobile installation. I have photos with details in the comments in the photo area of this group. I have a friend who uses a KT-100 with an Icom, but he has to manually press the tune button on the KT-100 and manually set the Icom to low-power CW to get the antenna tuned. You would need to do something similar with the AT-1000 when using it with the TS-480SAT. I think the AT-1000 is overkill for a 100W ratio like the TS-480SAT unless you are planning on adding a linear amplifier to your station.
Hope this helps!
73,
Avery, WB4RTP

Hi Avery,

many thanks for your comment.

I own already the AT1000proII and a linear amplifier for another combo, so it makes no sense to buy for each new transceiver the respective tuner. I agree that is not a pleasure to start the tuning cycle by pressing the tune buttom at the tuner especially you are mobile with the transceiver head in front of the car and the rest (black box, tuner etc) in the back.

Again many thanks for your comment.

Hey Guys, I think that I asked this already but just to remember. Too many marbles have rolled down the hill.

I have a AT-600 with an IC-751A and am wondering if a 120ft dipole on a balun or even no balun should work well on all bands. If I remember the tuner will shut down if it sees more than a 3 or 10:1 SWR.

So what is a good size for a dipole???

Not sure about the 1000 but the 200 proII I have has memories if it has used a frequency before it remembers it and if you transmit
near a stored frequency memory it automatically tunes.
at least I think it does, I'm old and so is my memory :)

6861. Z11ProII issue

Yahoo group: LDG-auto-tuners (2010 — 2017)

Topic: 6861 Message: 6861

Has anyone else experienced this tuner tuning when in the Bypass mode? (I am aware of the lockup issue when using VHF) When I've used this tuner in the past it was in a base station configuration and I never tried Bypass until now and my difficulty is when selecting Bypass mode the lights flash 3 times as they should but it still goes through a tune cycle when I transmit. I am using it with my FT-857D and when I monitor the SWR the tuner is definitely tuning in Bypass because you can see the SWR drop while transmitting as well as hear the relay chatter along with lights flashing. Therefore my observation is that although the lights indicate that I am putting the tuner in or out of Bypass mode it is always functioning as if it were not bypassed. It does it with and without the interface cable connected from the radio to the tuner. Am I missing something here?

Did you also put it in Semi-Auto mode? Bypass mode is only until the
SWR is above the threshold unless you go to Semi-Auto mode.

Hi Leonard,

That does seem to make the difference although I skimmed the manual again and don't see that in specific wording. I do see "The tuner may also be placed in "bypass" mode where it is electrically removed from the antenna system." To me if it is bypassed it is bypassed, not with caveats. Either way if this is how it is supposed to work I am satisfied. Thanks for your observation and taking the time to reply.

This is the way all the LDG tuners work. The idea behind bypass is where you have tuned well off the tune (such as band switch) so you are actually getting signal attenuation by the tuner. You can put it in bypass to get some signal strength back. Once you find some place you want to transmit it will tune back up when you start transmitting.

Putting it in Semi just keeps it from trying to tune up when you start transmitting. It also works if you have it locked to a tune. Comes in handy in a mobile where the antenna is moving in the wind and constantly causing the tuner to retune. Find one tune then go semi to keep that tune locked in.

Thanks to all.

"Problem" is solved. The AT1000proII will start tuning if he gets more than 20 watts output or so. The special cable for Icom or Yaesu is only to start the tuning cycle from the transceiver (with reduced output).

The problem you will have with the G5RV is the losses in the feedline, even, or perhaps especially, if a tuner has to match a really high SWR to the transmitter.

I had a standard G5RV up earlier this year, with about 75 or so feet of RG-8X from the tuner in the shack to the feed point of the twin lead matching section. I was perplexed as to why I was receiving few replies on 10M running 5 watts. One of the antenna gurus calculated that the SWR on the feed line between tuner and feed point was something like 60:1, that feed line losses were 12-13 db so that of the 5 watts leaving the transmitter only about .04 watts was making it to the wire to radiate. Some bands were OK but a couple of awful.

If I can suggest, why not run twin lead to the shack and use a balun/tuner there and let the power that heats the feed line get to the antenna to give receivers' AGC a workout?

The dipole with twin lead, matched by a AH-4 remote autotuner in my case, is MUCH better here.

Since you don’t say if you receive with your antenna I am assuming a basic laboratory situation where you tried to tune an antenna and tune a dummy load but never tried real life to know if any bands actually work. I have had that same model Autotuner tune the 10 meter band with nothing connected so it is possible that with a fault in a coax, connector etc. you could get it to tune on some bands.

Are you trying to just set it up so the tuner can kick the radio in to transmit in order to tune? If so why don't you just use Diodes to do a logic OR of the TX_REQ line so either the tuner of the amp can assert TX_REQ?

No. I’m trying to set the radio up, when I push the tune button on the radio it sets the radio to cw at min power, then sets the LDG tuner to tune when the tuner is finished it returns the radio to receive.

I have the AT-600 proII and as far as I can tell, LDG doesn't support program cables for the 450, 950 (except for the YT-450) or the new FT-1200 and 3000, only older Yaesu xcvrs. It's too bad. I had the YT-450 and it was a pleasure to have it talk to the xcvr and change modes for tuning. Maybe LDG will eventually get the hint and support the new Yaesu models

There IS a cable available from Yaesu for the FT-2000. Any chance the connector is the same for the FT-1200 or FT-3000.

The cable for the FT-2000 only works when you push the tune button on the tuner not the button on the radio. I used a LDG AT-600Pro for a year or so with the FT-2000.

If your tuner appears to be stuck in bypass mode, manually add capacitance or inductance and the tuner should come out of bypass for you. I had the same problem with my 100proII.
Good luck and 73,
Rick, N8GGO.

Hello everyone,

The tuner can never be "stuck" in bypass. Bypass is not a mode. It's just the settings of the inductors and capacitor at zero. Bypass is one of the settings the tuner checks for best SWR when tuning. So if no inductors or capacitors is the best answer, that's what it will pick.

We would not recommend adding capacitance or inductance, just to get the bypass LED to go out, but you can do that if the LED bothers you.

1. I stated that the tuner might "Appear" to be stuck. To a newer user of this technology; if they momentarily press the "Tune" button, it may "appear" that the tuner is stuck, or locked in the Bypass Mode.

2. If you are having difficulties with the terminology "Bypass MODE", you may want to have the manual for the 100proII rewritten.
Page 2 under " Tuning" mentions "Bypass Mode", as does
page 5 while discussing the " Bypass LED... "When in Bypass Mode".
and page 14 near the bottom discussing "Bypass Mode" with four more mentions of "Bypass Mode".

This forum may better serve those that have paid good money for their new tuners by answering their sincere questions with useful solutions to their problems rather than with criticism.

73 all and Good Luck,
Rick, N8GGO.

I keep posting a reply but never see it here.

As I now repeat, The tuner was connected to a dummy load, thus a perfect match. LDG indicated that the tuner will automatically go into "bypass mode" if it sees a perfect match and stay that way until the match goes away from 1:1.
I didn't see anything in the manual that indicates the above condition so I thought there was a defect since I could not toggle the bypass mode.
The tuner is working perfectly.

I do a lot of SWLing and I set my LDG 100 PRO to 1:1 match in to a dummy load which sets it to bypass. Then DO NOT Transmit. The antenna will be directly connected to RX. I can then listen 540 Khz to 30 Mhz without a problem.
I do wish The bypass would stay active until needed to deactivate. It is sometimes inconvient for the tuner to start tuning when I have it set in bypass. Overall I like the LDG 100Pro. It gives a match when I think it is perhaps impossible. Makes operation across the whole of 80, 40 and 20 with the fan dipole and 80 to 10 with the 88 ft inverted "L".

Just set it to semi mode (Func Auto toggles) Then when you want it to tune give a 1 second push of the tune button and it will start tuning when you transmit.

6895. Trouble with YT-450 Tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-08-15 05:33:39 UTC
From: nf.mayes@...
Topic: 6895 Message: 6895

I have a Yaesu FT-950 and an LDG YT-450 married up. About a month ago, the control from the PC and Ham Radio Deluxe Quit working, and of course the YT-450 quit working.

My first troubleshooting step was to unplug the serial cable from the tuner and plug it in to the FT-950 directly, and the control was restored. I e-mailed LDG, they said send it in, and I got it back with a note saying that it worked fine and they could find no problem with it. They suggested I try another cable.

So, I tried another cable, tried another serial port, tried another PC, used a USB to Serial adapter and I monitored the performance with a Serial Tester - an inline device with 9 LEDs to indicate the state of each of the 9 serial control lines.

In each instance, connecting directly to the Rig made the serial tester light up like a Christmas Tree. In each case, when I transferred the cable to the Tuner, 4 of the LED's went dark.

So, I believe that the Tuner is not working correctly. I am told by LDG that it is working correctly.

To recap, if the serial cable from the PC is plugged into the Rig, Serial control works. If the serial cable is plugged into the Tuner with a pass through to the Rig, serial control is lost.

What am I missing or not thinking of?

It was working, then quit. No changes were made to the cabling, equipment, software, etc. I double checked the three menu items that need to be set on the FT-950. They are all as per spec.

The FT-950 is working correctly with the serial cable from the PC going directly to the FT-950. If I try running the serial cable to the YT-40 and then on to the FT-950, the serial control quits.

My years of experience tell me that the Tuner is at fault, but the factory is saying that it works fine, but they don't have a Yaesu FT-950 to test it with. If that is true, why does the serial control die when it is plugged into the Tuner?

73's, Neil K7IPP

Subject: [LDG-auto-tuners] Trouble with YT-450 Tuner

I have a Yaesu FT-950 and an LDG YT-450 married up. About a month ago, the control from the PC and Ham Radio Deluxe Quit working, and of course the YT-450 quit working.

My first troubleshooting step was to unplug the serial cable from the tuner and plug it in to the FT-950 directly, and the control was restored. I e-mailed LDG, they said send it in, and I got it back with a note saying that it worked fine and they could find no problem with it. They suggested I try another cable.

So, I tried another cable, tried another serial port, tried another PC, used a USB to Serial adapter and I monitored the performance with a Serial Tester - an inline device with 9 LEDs to indicate the state of each of the 9 serial control lines.

In each instance, connecting directly to the Rig made the serial tester light up like a Christmas Tree. In each case, when I transferred the cable to the Tuner, 4 of the LED's went dark.

So, I believe that the Tuner is not working correctly. I am told by LDG that it is working correctly.

To recap, if the serial cable from the PC is plugged into the Rig, Serial control works. If the serial cable is plugged into the Tuner with a pass through to the Rig, serial control is lost.

What am I missing or not thinking of?

6898. Tuning the YT-100 on 60 meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-08-15 18:44:24 UTC
From: hdcoley2@...
Topic: 6898 Message: 6898

If you have not yet discovered a workaround for being able to initiate a tuning procedure of the YT-100 on the pre-programmed 60 meter channels of the FT-857D/FT-897D, the easiest method I found was using the key line on the ACC jack. I have read suggestions of using the CW key line, but that can be a little more involved if you need to switch from electronic keying in order to transmit a CW signal for tuning. And if you intend to operate USB, then it involves switching modes and maybe keying methods as well. This way you can leave settings as they are as the radio will always transmit a CW signal when the ACC key line is closed regardless of mode or other settings.

By closing a connection between the ring and sleeve contacts of the ACC jack, the radio transmits a CW carrier for the duration the contacts are shorted. I fashioned an external momentary switch wired to a 3.5 mm stereo plug connected to the sleeve and ring. The tip is not connected as it is the ALC line. The switch I use is a surface mount tactile momentary switch which can be double sided taped somewhere on the case of the YT-100 and plug the short cable from it into the ACC jack.

Initiate a tuning cycle, and then immediately press and hold the momentary switch and the radio transmits a CW signal for the tuning cycle to complete. As soon as the tuning completes, just release the switch.

Of course power is not reduced, so you may wish to temporarily drop power down while tuning which is what I do, and of course it will usually only be necessary to tune on one unused channel in order to operate on the desired channel.

I personally prefer not to have the MARS/CAP mod on my FT-857D as a workaround.

It was working, then quit. No changes were made to the cabling, equipment, software, etc. I double checked the three menu items that need to be set on the FT-950. They are all as per spec.

The FT-950 is working correctly with the serial cable from the PC going directly to the FT-950. If I try running the serial cable to the YT-40 and then on to the FT-950, the serial control quits.

My years of experience tell me that the Tuner is at fault, but the factory is saying that it works fine, but they don't have a Yaesu FT-950 to test it with. If that is true, why does the serial control die when it is plugged into the Tuner?

Regarding power...under the section “Antenna Considerations” on page 12 of my FT-857 manual it indicates that if the SWR is greater than 1.5:1 it will automatically reduce power output therefore using a tuner should not create undesirable consequences.

Bill,

I tried two serial cables, two serial ports, 2 PC's and one USB-to-Serial converter in a matrix. Any and all combinations resulted in the same failure.

Like I said, it was working fine for about two weeks and then quit. Period.

I've learned that the art of troubleshooting a system is to isolate out the "black box" that is failing, by swapping out the other "black boxes", resetting the "resettable" "black boxes" after each swap, whether they be a module or board or cable or whatever. Eventually you will isolate the failed "black box".

Unfortunately, in this case, I did not have another YT-450 to swap out and no easy way of getting one. The Rig rally didn't figure into the equation, because the RS-232 tester was showing that the RS-232 lines were being "perturbed" when connecting to the Tuner, regardless of what was or was not attached to the serial out of the Tuner.

I was a Tech for 10 years and a Degreed Test Engineer for 30 years.

Per your below, do all combinations work without the tuner in line with the serial data and under all circumstances?

To confirm, you said it worked with the tuner in line for how long? Was that also for all combinations as you note below?

6904. RC-100 T-bias controller blown! Fixed with suggestions!

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-08-16 20:06:59 UTC
From: mpupeza@...
Topic: 6904 Message: 6904

While playing radio at a campground in my trailer, I decided to do a A/B comparison between a 12' whip tuned with the RT-100 at the top of a 25' aluminum pole and a 33' horizontal wire fed with a 9:1 Unun at the top of the same pole.
Sure enough, I inadvertently swapped the coaxes and let out all the magic smoke from the RC-100 controller.
My bad!
When I opened it I saw that there were 4 mini SMD inductors marked L4, L5, L6, L7 burned and melted.
Since the RT-100 manual suggests an inductor up to 100 uHy. I decided to use a 108 uHy that I had, BUT not without protection. I installed a fuseholder on the back and a LED on the front above the Status (Power) LED.
Now, if the 1.5Amp fuse blows, the LED should light up if there is the RT-100, or a short, connected.
It seems to work well and I recommend that a fuse be installed in that box. It could happen to YOU!

Good point. Power should be folded back by the radio as you pointed out when the SWR is high, but I did notice it output close to 100 watts much of the time when it is tuning. The YT-100 selects AM mode and I never see the power exceed 30 watts. Since it cannot set AM mode on 60 Meters, the radio stays on CW or USB except it transmits CW only when the ACC contacts are closed. My main concern with reducing power was to avoid causing interference and not trust the radio to fold back power. If the channel is clear I suppose transmitting CW at 100 watts is of no real consequence for interference. My ERP is closer to 65 watts accounting for feed line loss into the dipole I am using, so maybe I am too concerned. Anyway, I was happy with the workaround using the ACC socket solution.

The YT-450 doesn't auto tune. It memory tunes, so you have to hit the tune button when you switch frequencies or bands. IF you have tuned at that frequency before it should then set itself in a couple of seconds from memory, instead of of going through the complete tuning cycle. If you haven't tuned at that frequency before, it will go through the complete tuning cycle and then store that info for that frequency so the the next time it can memory tune.

How can I reset the YT-100 which I use for my FT-857? It's giving me troubles on 17m. With it connected to my laptop, I get high swr and beeping (rf feedback?). When I disconnect it from the PC (using RT systems 62 USB cable) I can tune 17m ok and have no problems. With the connection to the PC, I can tune all other bands ok.
Thanks for the help,
73

Subject: [LDG-auto-tuners] YT-100 reset

How can I reset the YT-100 which I use for my FT-857? It's giving me troubles on 17m. With it connected to my laptop, I get high swr and beeping (rf feedback?). When I disconnect it from the PC (using RT systems 62 USB cable) I can tune 17m ok and have no problems. With the connection to the PC, I can tune all other bands ok.

Thanks for the help,

73

Thanks for the info Jimmy. I guess I'll have to search for the RF feedback on 17m. I'm using a G5RVjr (40m-10m) and I noticed that after a wind and rain storm a while back the ends of the antenna are touching some branches and leaves. This may be one of my issues, but I think it has to do with the PC/CAT cabling.

I am KK4VUZ, Virgil.

I bought a new AT1000PROII about a month ago and was tuning an inverted V center fed dipole and "smoked" the tuner. So, I completed the form and sent it back to Maryland.

They have had it since August 13 and I was interested in their progress. When I went to the website I found the following...

DO NOT Call or e-mail to ask about Status or Updates: We will promptly contact you when your repair has been completed. We are unable to provide call-tags for repairs and do not cross ship units.

Is there anyway to get an update on equipment being repaired?

Virgil-
That is 10 days. They were closed for vacation for more than a week of that time. They did announce the closing, on this list.
Don’t give up. Dwayne and his “People” are probably VERY busy, playing “Catch-up”.

LDG is a very difficult company to get info from. I'd also be interested in why/how you can smoke a tuner on a dipole. How much power are you running? How much do you use when tuning?

Virgil and all. We used to say repairs take up to 4 to 6 calendar weeks for repair, but that was just too generic and looked like a long time. We rarely ever reached that maximum time frame anyway, but we said that as a catch all. Now we just say it will be done as soon as possible. It's an odd occurrence at LDG that we get more than 7 or 8 units in for repair, so most of them are done in just a week or two.

The number of units sent back is so low that we only have a part time person that goes over the really troubled units a couple of days per week. We have a first level technician that looks at them to see if the problem can be replicated or not and can send the unit back (75% of the time there is no issue) or pass it along to a technician. The tech receives units a couple of batches per week and goes over each unit to make an initial determination if it can be repaired or if it's beyond repair.

Finally, if it can be repaired, the technician will do the repairs in the order that they receive the units. There is no way to tell at this point how long it will take to repair any individual unit. It completely relies on the number of units ahead and the complexity of any units already in the queue.
So you see, there is really no way to individually track down any particular unit while it’s in process. This is why we say we’ll contact you when it’s complete. It could be complete at any one of the several steps. It’s by far, the most efficient system possible give the resources.

Taking the time to set up a tracking system so a few units could be tracked through each step would be extremely inefficient. Obviously we could do it, but it would certainly add a significant amount of time to each unit sent in for repair, whether they we returned with the first few days or it ended up with tech for a detailed checkout.

Everyone gets an e-mail as soon as we are finished. We make that very clear. Asking for some kind of status along the way only delays the entire system.

We’ve been doing this a few years and know that there are more customer oriented systems out there, but none are more efficient and certainly not faster than what we currently have implemented.

I hope this helps in understanding the system.

Dwayne, Obviously my comment was supportive – not negative. As I said, “I THINk” I saw the email as mentioned by others. You guys have a very good product – mine works very well tuning a homemade vertical on all bands between 75M and 12M. I usually tune at about 50W, then run a kW through it. No problem yet…! My next purchase will be the external meter as watching the LED bars drive me nuts (-: .

Please don’t get sensitive on us, and keep up the good work.

Best regards,

Bill – K4IZE

Dwayne,
Your explanation helps a lot. I realize I am only one customer but if I had concerns...

My I suggest that you consider putting your explanation to me on the website on the same page as the "DO NOT CALL". I know it would have made me more understanding and given me more hope about the time line required. As it stands, you know how good you are but a new customer like me doesn't and just think you are another faceless corporation sitting on my $400+ investment until it is convenient for you to get around to fixing it.

THANK YOU for taking the time to answer me. I feel a lot better after reading your email.

Hi Bill,I really try not to be overly anything. Normally, the tone is kept as neutral as possible. Too strong and it comes off as a bullying. Too weak and it looks overly sensitive. Just the facts and it's too sterile. There may not be any way to do it properly. Oh well, we'll keep on trying.

To Virgil, I agree with you and we'll look at better ways to phrase that section. Thanks for your input.

I MUST chime in.

A couple years ago we "fried" a LDG 4/1 balun during Field Day because of some weird impedance with a portable dipole fed with window line. We were running CW, 100 watts, and on 40 meters the impedance was "just wrong."

I was asking for info on the type of core which was used, so I could find one on the open market and copy the size and number of turns from the "fried one." Instead of telling me the type, etc., I was floored, surprised beyond belief, overwhelmed, when a complete, new toroid, all wound, and ready to be soldered into the old case came in the mail.

Customer service, over and beyond the call of duty!

10 stars out of 5 maximum, IMHO.

(Note, I had already purchased a new balun, and for the price of the unit, it wouldn't have made sense to send the old one back for repair!)

Hello to the group.
  I have been quietly reading all the responses concerning
LDG products,and decided to put my two cents worth in.

  I was introduced to LDG with a Z11 that came with a radio I bought
used .
 I followed the set-up procedures,and the instructions in the owners manual
that came with it , { yes I do read the instructions on ALL "new stuff " I get.
  I never had a problem with either unit.

 I sold those for what I paid for them,and bought a new LDG 600 pro tuner,to
go with a "new" Ameritron AL811 and a "new to me " Icom IC737A,and again ,
read both manuals before turning them on .
Again," never a problem with the LDG ,but the AL811 "needed" to be updated
to the AL811"A" .   and I sold the LDG600 ,and bought a brand spankin' new
LDG 1000PRO2 .....I have had the LDG1000PRO2 for about two years,
never a problem with any of the LDG products .
  I have had different manual tuners,from Heathkit,and MFJ before getting

the LDG tuners .   I could have saved myself a lot of money if I would have
gotten an LDG in the first place,but was concerned about " new products from
a new company .... well live and learn .... LDG makes good quality products,
and I would not hesitate to but from them again !   Ihave been a HAM since 1978,
so I am " old school ", and would highly recommend LDG products to "newbies",
Keep up the good work Duane and the people at LDG .
73,
Art

Hi, gang,

My attic-mounted Z11ProII is being weird.

On HF, it tunes and hears without incident.

On 6 meters, it tunes fine on TX but it's deaf on RX.

I can switch to an attic mounted 6-meter dipole, and it hears and transmits just fine, so it's probably not my radio.

Thoughts?

Thanks!

I have one of these connected to my IC-7000 and it's always work very well. I have heard that you can add batteries to the Z-11Pro2. Is this possible with the model I have? It would be good to detach it from the ICOM and use it on it's own when portable with another ig.

There should be a section in the manual called "Installing an internal
Battery"

Got the wrong title it is "OPTIONAL INTERNAL BATTERY INSTALLATION". If
you don't have the manual you can download from LDG web site.

On page 9 of the manual, you will see that batteries can be installed
with an optional battery pack that would hold 6 or 8 AA or AAA batteries .

 On the same page,you will see the connecting location for the leads.

73,
Art

6932. RT-100 questions

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-08-29 15:03:37 UTC
From: Jim Allen
Topic: 6932 Message: 6932

I have been using the RT-100/RC-100 combo for a few months now and notice that on some bands, especially 40M, it doesn't seem to remember the settings for each frequency. Also, I run almost all the time at 5 watts. When I increase the output towards 100 watts, it seems to lose the tuned setting, the SWR leaps up erratically and I have to re-tune. This is a relatively recent development. When I first started using this, I did not notice this phenomena.

A couple of possibilities come to mind, including RF on the coax, and of course, the RT-100 is malfunctioning. The Omni VI+ might be going berserk, too, I suppose. How should I proceed to figure out what is going on.

I have the RT-100 feeding a Balun Design unun 4:1 to a S-9v31 clone.

TIA

From: cdruhl@...
Topic: 6934 Message: 6934

I was tinkering with a home-brew end-fed antenna with a balun for field use and apparently got RF into the shack. I keyed up my Morse key once and the AT-897 Plus has its LED flashing continuously ever since.

I guess I'm sending it back for repair?

What a bummer!

Have you checked the SWR without the tuner in line? Although not probable, it may be that the SWR is too high for the RT100 to match it. Or as previously noted there could be a bad connection, water in the line, etc. John

This is puzzling as it matches just fine on reduced power <25 watts, then after advancing the power and sending for a bit, it suddenly appears to lose tune, the SWR and Output needles swing wildly. This doesn't happen every time, either, only some of the time. I don't know if it is frequency related on the low end of 40M. There is no water in the line; it hasn't rained here since it went into service! The connections seem tight.

I wonder if the transmitter might be going into parasitic oscillation or something in particular circumstances, combinations. The radio is about to be back to the factory for a check up as it has no output power on 160M and almost none on 30M... I don't know why. So something may not be quite right in the radio, too. I intend to try it with another radio tomorrow.

The tuner is a veritable "black box", no indications of what it is doing inside, AFAIK. I'd like to come up with a means of isolating each part of the "system."

I can't seem to access the RT-100 manual at the moment, but tell me. Is the power rating in PEP?

If so then it's not rated for CW/DIGI at 100W, rather the max you'll be able to push through it before it starts heating up (and the SWR changes) is about 30W. I see this behaviour with my AT-100, if I run more than 30W digital things start to get hot, and the SWR goes out pretty quickly.

This is a common thing a LOT of manufacturers do, An AT-100 is really only capable of about 30W on CW or Digi, and I'm pretty sure if you check the manual the 100W figure will list "SSB" or "PEP" next to it.

As I suspected it lists the power rating as:

0.1 to 100 watts SSB and CW peak power, 30W on digital modes.

If you're running more than a 30W carrier, it'll start to get hot. When it gets hot the inductance changes and your SWR goes funky.

The manual says "0.1 to 100 watts SSB and CW peak power, 30W on digital modes."

If this doesn't handle 100 watts CW and SSB, then it was sold under a false pretense.

Be that as it may, I run more than 5 watts about 5% of the time, never more than 100 watts, 99% CW, and I've not noticed this phenomena on other bands.

I have another thought, that RF is getting into the mix where it's not supposed to be, maybe common mode etc.

Is it desirable to have a CM choke between the tuner and the radio with one of these tuners? I fed the S9v31 clone with a 1:4 unun, the RT-100, then ~25' of RG-213 back to the shack. I have been under the impression that CM chokes are not particularly necessary with these remote tuners, the balance that they enforce being done at the tuner. Maybe this is the problem......

Joshua,

The duty cycle rating for CW and Digi is not the same thing. Digi is like RTTY or slow scan, it's 100 % duty cycle. CW is much less than 100%.

Dwayne Kincaid

As Dwayne has said before, if the toroid cores overheat...the damage is done. They will be more likely to overheat again and ultimately result in catastrophic failure of the core. It would be prudent to check the tuner's toroids for any heat damage (e.g. cracks in the cores, scorching, etc.). If there is sign of overheating, you'll want to have the tuner repaired.

If the tuner isn't the cause of your spiking SWR, then as others have said, you might check for moisture in the feed line including moisture in lightning/static arrestors. Also ensure that your 4:1 balun is rated high enough to withstand high voltages and/or current without becoming saturated.

73,
Brad KA3YAN

Topic: 6932 Message: 6943

I think I can say without fear of contradiction that moisture in the feed line isn't the problem. It hasn't rained since the tuner and coax went into service! There is no irrigation out in that part of the property, on the edge of Indian country.

I will take the tuner off and open it up to look for heat damage. There has never been more than 100 watts of CW through it, so I hope that hasn't happened. If it can't take 100 watts of HF CW routinely, then it is worthless for almost all users. My AH-4 has handled that for years without a hiccup. I'm thinking RF in the feed line, common mode type stuff is more likely.

Topic: 6932 Message: 6945

My AT-1000ProII manual states its SSB rating is 1000W, CW 750W, and RTTYPacket/PSK31 400W. I just ordered an AT-100ProII, for which the rating is 125W for BOTH SSB AND CW.

The relative differences for SSB and CW for the 2 tuners are confusing. Going back to Dwayne's comment, is 125W on the AT-100ProII too high for normal CW ops? If so what would be a safe level for normal use?

Thanks,
Howard

See rsgb.org/main/files/2012/11/emc-leaflet-13.pdf , and scroll down to "Table 4 - Duty factor considerations for some typical Amateur transmission modes". The RF safety aspects are useful reading, too. Note the difference between normal and compressed SSB.

The issue is what voltage the capacitors can withstand *and how much heat the cores can take*; a low duty cycle has less chance of damaging them becasue they have time to cool down. High voltage capacitors can be cheaper than high wattage cores, but an overheated ferrite core will change value permanently if it gets hot enough. See below.

I once saw an "100 watt PEP" 4:1 (200 Ohm design impedance) Balun melt its plastic case when it was used at 100 watts "running" a frequency during Field Day. (I had a much larger one available and we replaced it.) The higher the SWR, the more power the Balun core (or a tuner's cores) must dissipate , so what started out as "100W SSB" for conversational SSB was probably exceeded several times over.

IIRC, the manufacturer sent the owner a new and larger core to rewind it.

FIWIW department. It may be a good idea to use an antenna bridge to see what SWR the tuner must deal with. One "1500 watt" Balun core at my station got hot enough to boil spit (!) and become useless on just 100 watts. To quote the Beatles, "Now I'm a Believer ...".

This exact same thing happens to me except at a much higher power... when running barefoot (100 watts) all is fine but kick in the amp and transmot 700 watts and SWR goes way high and tuner appears to go out of tune. This is with the AT-1000 or either of my AT-1000Pros so it's unlikely that it's the tuner.

I'm convinced I have a problem with my antenna (160-meter inverted V fed with ladder line) that only shows up at high power levels, perhaps a loose connection or one of the wires touching a branch or something. The antenna wires are insulated but maybe the insulation has worn where the wire touches a branch and arcs over at high power. Maybe.

I've already switched baluns to no joy. I'm hoping to be able to get out there today and find the problem.

Rick:

Quick question... If you were to transmit at higher power using a continuous carrier and watch the SWR (tuned SWR, not what the antenna is presenting to the tuner), does it immediately become erratic or ramp up to a point where it's a problem. If it's the latter, it's probably heating in the tuner. In that case, what's the SWR for that band with the tuner in by-pass mode?

Otherwise, this could be an indication of stray RF or common-mode RF current on the transmission line that's getting into the tuner control circuits or other things. Do you have any other indications of stray RF at higher power?

6949. AT200 Pro help

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-09-22 14:34:45 UTC
From: ka9p@...
Topic: 6949 Message: 6949

Having a bit of trouble with my AT200 that's worked great for the last 4 years, and would appreciate any sage advice.

I run the tuner in the automatic mode to remotely tune an 88 ft center fed zepp, and it has stopped tuning on any band but 80 and 40 meters. Antenna appears ok and unchanged.

The tuner will infrequently try to cycle on the higher bands but when it does, I get the two flashes of a row of LEDs which I believe signals an error. I've been through the manual, read and reset everything suggested, but the result is unchanged.

Does this sound like a failed tuner, or is there some possible operator error involved I should continue to chase? Or some testing with sample loads of various types I might try to see if the tuner is still in spec?

Thanks, Scott

Good morning, Chuck.

It becomes fairly erratic fairly quickly... don't know about "immediately" but within a few seconds. I use the same tuners on my other inverted V (also fed with ladder line, a balun, and a short length of coax to the tuner) which is even farther off-resonance than the problematic one, and don't have this problem. Also, with this antenna, the problem is relatively recent... I used it for many years at 800-watt power levels with no issues.

As for the SWR that the antenna presents (tuner in bypass mode), it is sky-high most of the time. I use both of the inverted Vs on a wide range of CAP and MARS frequencies as well as amateur ones, so it's a lost cause to try to use an antenna that's anywhere near resonance for all, unless it's one of those T2FD "radiating dummy load" antennas which I also have (for CAP ALE).

I have no other indications of excessive RF in the shack... lots of RF in the shack would show up (and has in the past shown up) as lines across my computer screens, among other things, and taken to excess would interfere with my computers (four of them) running here in the shack, causing them to reboot and such, and nothing like that happens.

Are you using a balun 4 to1 or 1 to 1 from the balanced line to the LDG tuner?
I found trouble only with 17 meters with my 1 to 1 balun using my 88 foot doublet. All others OK. Need to try 4 to 1 and see what changes I find.

Well you may need a 1 to 1 on 80 as the impedance is already low and the 4 to 1 may make it so low the tuner has problem finding match. That is why I take the advice of the sages and use a 1 to 1 now. I am going to make a 4 to 1 to try on 17 on mine.

This sounds like local RF being detected as reflected power. I've been reluctant to put such a sensitive tuner at the antenna because of an expanded-band 10 KW AM station less than a mile away. One "fix", if tuner memories are unaffected, is to store the settings for each band or band segment, then set the tuning threshold at 3:1.

One possible fix for the AM station is to install an open quarter wave at the AM freq on the antenna side of the tuner. That should keep its signal out of the tuner.

Dr. Don:

Keep in mind that this will cause a low-impedance across the line every odd multiple of the frequency in addition to the design frequency. Assuming 1 MHz, that's every 2 MHz also above the design frequency. Probably not going to work out well, not to mention the length required for that stub. :)

Might cause less problems to put a series resonant LC network across the line for that frequency, but I'd want to think about that a bit.

That is a possible result. However either a coax stub or an LC trap can be used to see if the erronious reflected power reading is resolved. If not another solution need be sought. If resolved then possibly another means to remove the RF Is needed. Perhaps like adding a load to the output of mixers to absorb the unwanted products.
First it must be determined what the problem actually is before deciding what solutions to use.
Years ago we had a problem at a BC station where I worked. There was a big null in the pattern. Found a local chicken farmer had installed a LARGE multiturn wire antenna and was using the Rf to power heaters for the chickens or such. Paying a small monthly power bill and dismantling the antenna solved the null problem.
There are many things that may help, but first have to determine the problem.

6961. YT-1200 Update

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-09-25 03:18:39 UTC
From: ldgyahoo@...
Topic: 6961 Message: 6961

Just a quick update to say that the first shipment of the new YT-1200 has been shipped to dealers this week. All current orders have been filled.

Thanks for the bandwidth,

Dwayne Kincaid
LDG

6962. AT-100ProII port isolation

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-09-29 18:44:54 UTC
From: steve.lenaghan@...
Topic: 6962 Message: 6962

I have noticed during some dummy load tests that there is quite a bit of feed through from the inactive port (antenna) when the second port is connected to a load. Is this normal? The down side is that when operating MARS-ALE into dummy load the radio behaves like it was still connected to the antenna. For this and EMCOM work it could lead the operator to think he was not getting through.

I have determined that the loss between terminals is about 20db and on JT65 this still allowed adequate signal decoding except for marginal stations.

Got mine from HRO. Learning how to use it with my Yaesu FT 450D. Only issue--loud sounding when tuning. Maybe just needs to break in. Also mounted on my power supply. Pleased otherwise.

Tom it uses relays to switch the various L C combinations, so the chattering is normal. The only thing that will keep the noise down is faster tuning as you populate the memories with various tuning steps.

I guess the only separation between connectivity between each antenna port is a relay, which probably doesn't give total isolation. I guess feeder and connector quality might have some influence if any signal could reach to the circuits though the common ground. I have not had a particular issue with the vast array of LDG tuners I have owned, but then I only operate SSB/CW.

I guess the same thing could exist on antenna A/B ports on the radio itself. I wonder if it would help to replace the jumper wire from the socket to the PCB inside each antenna port on the Tuner with some decent coax.

Hi mike,

I have a similar issue, when switch the tuner to bypass mode, it doesnt
pass 100% direct from radio to antenna, i do have some swr inserted, just
got 100% bypass when turning off the tuner, and that should not happen.
The issue has bigger effect on 50mhz
Using a AT-1000pro tuner...

Cheers

6967. Integrating a AT-600 Pro II with my FT-DX1200

Date: 2014-10-10 13:33:10 UTC
From: n0xoc@...
Topic: 6967 Message: 6967

I am in the process of reconfiguring my shack. I've upgraded my rig to a Yaesu FT-DX1200 and will be adding a AL-811 600w amp. I need a tuner for this setup and am heavily leaning towards a AT-600 Pro II.

I've been using a YT-450 with a FT-450D, and now, the FT-DX1200. I like the ability to do a single button tune. What is the best way to integrate and operate this tuner? Is there a connection cable that I can buy or build that would integrate the FT-DX1200 to make the tuning process more efficient?

Thanks in advance for any information or suggestions.

The radio is an FT897 and I don't have the VHF/UHF port connected so it is not radio related. Another issue is the memories. I operate mostly JT65 and some MARS channels, less than 50 max. When I am using ALE the tuner will decide, that a full tune is needed during sounding. With 2000 memories I expect this should not happen.

If you use balanced feedline, twin lead, ladder lead, etc., 130' works well, fed at the center. The tuner can match that pretty easily. The biggest factor is height, no matter how long or short, or how it is fed. Get it up high and in the clear and it will do quite well. It won't be like stacked monobanders at 120' no matter what, but much easier to carry to your site and put up!

I've had this a 32' at the center, drooping down to ~12-15' at the ends and worked all over on 5 watts.

I have been using an Alpha ProMaster with my Yaseu 897 and matching Ldg tuner; neither are the D model. This antenna tunes from 6 meters to 160. Today was my first day with it but I was hitting Michigan, New York & Alabama from Fort Worth with about 8 watts (qrp) and getting 5-9 reports on 20 meters. So far I am happy with this antenna.

From: da6tec@...
Topic: 6977 Message: 6977

Hello all,

I have recently purchased a Z11 Auto tuner (second-hand) to use with my FT817, it is one of the older ones ... all black metal, 4 toggle switches, tune button and 4 LEDs.

I have 2 questions, that I have not been able to find answers to on this Group:

(1) It looks like a modification has been made to the rear of the unit ... an additional 3 way toggle switch (between the two x So239) and two x 2mm 'test sockets' next to the switch. Anyone have an idea what this might be for?

(2) When tuning on 2 bands (80m and 30m) the tuner lights the orange light (2.0) LED, when I press the Tune button the tuner then automatically find a better match and the green (<1.5) LED lights up. How can I set it up to find the best SWR automatically (like is does on the other bands)? My switch positions are:

Power 'Up' Auto 'Up' Cap 'Middle' Ind 'Middle' With the tuner was a leaflet for an upgrade to Firmware v1.6, I am assuming that is the firmware version I have.

Grateful for any advice / guidance.

Topic: 6977 Message: 6978

I can only guess a purpose for the modification: the two test sockets could be for direct connection of an end fed antenna and counterpoise or a dipole without a feedline, as one might use for a portable operation. The switch could then transfer the output from the coax connector to the test sockets. You could try putting a dummy load on the normal output to see if the switch disconnects it, and then putting the dummy load between the test sockets and see if they function as output terminals in the other switch position.

The CAP and IND switches are spring loaded and always in the middle position except when pushed momentarily up or down, individually to tweak the capacitance or inductance, and down together to bypass the tuning elements.

I also use a Z-11 with an FT-817. I found that the FT-817's SWR indicator sometimes indicated a higher SWR than the Z-11 found automatically and by using the CAP and IND switches I could make the FT-817 see a better SWR and produce higher power output. I wrote to LDG and got instructions on how to calibrate the Z-11's internal SWR bridge using internal trimmer capacitors - I can send you additional info if you wish.

I did not systematically test the difference between the Z-11 and FT-817 SWR indications to see if it only happens on certain bands or with certain antennas.

Steve I wonder If electronically the antenna is changing i.e. in wet conditions. Or perhaps there is some stray RF making getting a fix problematic. Another thought I had was if the SWR at the frequencies you are trying to operate on are marginal, the tuner might opt for a full tune.

I have a 135' OCF hung between two large pine trees (60') with insulators away from trees. It is mostly dry here so that is probably not an issue. It is fairly high off the ground and little to interact with up close.

As for stray RF, this is a tuner that is full of RF, and lots more when it is unturned. So if anything should be tolerant of RF it should be the tuner. Trying to deflect by blaming RF is not flying with me. I have worked on ¼ MW broadcast (821A2) that tolerates 30 KW of reflected power without jumping tuning.

I'm more concerned with RF leaking OUT the power cord than in.

I moved the threshold up past the SWR displayed and still get retunes. A military grade B&W Broadband is going up in the spring for ALE use.

Speaking of RF. I have a AT 1000 PRO II. That has developed a issue of high SWR while running my amplifier. So I figured it was RF getting back into the tuner. I have a field strength meter in the shack and it shows no RF. I put ferrite beads on both feedlines and on the power cord. Also put a choke outside my shack. Nothing helped. I switched the antenna feedline to antenna 2 position and the issue is gone.
Can someone explain this to me?

This is the 2nd AT 1000 PRO II That has had a issue with ant. 1 position. The 1st one had a issue with the receive relay.

No reset on LDG tuners. The memories in the tuner are for your antennas not the radio. The SWR will be the same on all radios give or take a little depending on the SWR circuit in the radio.

Some of the early tuners had reset capability but it was removed in the more recent ones. I always felt it was a good idea for example if going to a completely different or new antenna. In actuality the tuner will still learn a new or different antenna and just overwrite the old memories.

Neil,

We've never seen a valid reason to provide a way to reset all the memories in the tuner. Since the tuner will fall through to a full tune anytime the memory recall does not provide a good match, each tune will reset the current setting if needed.

So it's exactly the same as if there were no memories at all when you change antennas.

Changing the radio (in theory) should make no difference at all.

My thought is that one may find a different SWR reading depending where the meter or tuner is placed within the transmission line.

Do you find that the SWR readings of the tuner and your radio, may disagree (on some bands they agree and on another they may not), depending on which HF band is used?

I have the same issue with my LDG AT-897 on 60M. This may or may not be the same issue as yours -- you have good antenna and feed line confirmed and the tuner doesn't seem to see RF to generate a match and won't do anything on 60M. The LDG tuner I have -- and yours might be the same in this sense -- sends an AM carrier after changing the radio's mode to AM automatically. We are limited to SSB and CW on the 60M band and my radio, at least, won't allow me to select any other modes so you are seemingly out of luck as my LDG tuner, at any event, can't be programmed to tune on anything but AM.

To generate a tune, I find an empty channel with no activity and either set my rig to CW or SSB, set the power to QRP level (no more than 20W in any event -- I run 100W max), start the tune process and then immediately tap out my call sign on the key or speak my call sign if using phone and then the tuner senses RF and starts to finds a match. I repeat my call as necessary until the tuner finds its match and stops and usually send out QRL? or "is this frequency in use" or simply "testing" or something like that.

You should not have to repeat this tune process if you change channels unless your antenna has a very narrow bandwidth on 60M.

Why LDG does not put this issue in the manual, I know not.

ciao,

Chris N3GBJ

Sounds like more of an FCC regulation issue to me and the LDG tuner does a great job tuning on SSB or CW which are both way less than a full duty signal. How many tuners can tune while talking on SSB?

Is your transmitter capable of transmitting on the channelized 60 meter band? If the transmitter will not key up the antenna tuner will not tune.

As Bill asked, what is the difference between CW key down and unmodulated AM?

I always tune my AT100 pro with 20 watts unmodulated AM and it always works perfectly.

The tuner doesn't like your antenna on those frequencies.

For a test, try changing the length of the feed line from antenna to the tuner. This can make a difference in what SWR the tuner sees. The right length and the tuner may work on 60m. The down side to this, the antenna may not work on another band..

Most LDG tuners have a serial passthrough port. I recommend to cross check the user manual. It will only interrupt HRD during an actual tune.

From: da6tec@...
Topic: 6999 Message: 6999

Old style Z11 (not pro)

I notice that it is possible to change the SWR threshold on the Z11 Pro versions (ie. that SWR level at which the tuner will autotune). On my Z11 it will not go into autotune unless the SWR is 3:1 or above - this is the version with 4 toggle switches and a row of LEDs - no function button.

I would very much like to reset to 2:1 or above. Is it possible?

Many thanks. 73 Carl

Any Tuner LDG that tunes with RF sensing will be fine. I prefer the Z11 Pro... I like having the ability to tweak match manually if required. Another advantage of tuners like the Z11 Pro, they are not dedicated to any specific radio brand. I've use mine with many brands of radios, always with great results. If you change radios your tuner is still good.

On your FT-450, program the CS button for tuning.. it will switch to CW and transmit a low power carrier. When the tuner senses the RF it will tune to the best SWR. No additional cable between the radio and tuner is required, only the coax. Works great..

73... Ken - VE5KC

Greetings to the groups from a new kid, (not so much of a kid)

I had a thing happen to me the other night that I have no answer for, hopefully somebody in the group can help.
My station consists of the following:
Flex 5000A , Amertiron ALS-600 in the LDG AT-600ProII tuner into a 260ft loop at 30ft.

I was on 3523 listening for the FT4, all tuned up, etc ready to pounce. I finally heard him through the noisemakers (being nice), called and
my leds on the tuner went crazy. Checked the error message and said I was “overdriving it”.
Now I have been tuning at 20w since day 1.
On the Flex it is a tab setting that you click up/down arrows to set, so it is not something easily changed. I checked the tune setting in
the Flex and somehow the setting was changed to 100 watts. I reset it to 20w and from then on, I cannot get the tuner to find a match.
It goes through the tuning cycle but no match. What really bothers me is that I can power down/up the tuner on a strong signal (WWV)
and not see any difference in putting the tuner online or off. I tried this with several stations besides WWV. I can bypass the tuner and
see the same stations at the same signal strength. I went through the usual troubleshooting tactics i.e. changing coax, etc.
The kicker came when I remembered I had a Z-100plus autotuner in the closet, so out it came. I hooked it up and everything is running
smoothly. Made a couple q’s (unfortunately not the FT4) to check it out.
I have read the book and I cannot find anywhere where you can reset the tuner to factory defaults. Unplugged the tuner power with no success.
LDG is closed Fri, Sat and Sun , so no help is forthcoming from that end.
Has anyone experienced this happening or similar and any corrective actions?
Thanks very much and 73
Marty

Date: 2014-11-08 04:21:13 UTC
From: vmlist2@...
Topic: 7004 Message: 7004

Hi Folks,

I've searched until I am bleery eyed, but I can not find out how the radio inputs on this / these things are wired or what they expect.

The 751A outputs a reference voltage and a band voltage for an autotuner, but I just come up blank on what the LDG tuner expects.

The 751A may be too old for the cable to be effective and may not even matter with the auto-tune.

After all this searching efford, I'd love to know what the LDG expects.

Thanks MUCH!

The LDG AT 100 ProII has no control cable input. The only connections are power (low voltage DC), one RF (UHF connector) for the Transceiver, and two RF(UHF) connectors for two different Antennas.
Control is by buttons on the front; display is by LEDs. in action, the unit detects RF in, measures SWR, and makes adjustments according to the controls you set.
It should work well with your rig.
There are other LDG tuners that are partly dedicated to specific rigs and will control Mode and power level (by CAT control) for tuning.

The LDG tuner has a built in frequency counter, so there is no need for any band voltage from the 751A.

From: Robert Biamonte
Topic: 7002 Message: 7008

Marty,
I use the AT-600ProII with an Elecraft K3 and I had to set, through the Menu, the Tune Power to 4 watts to avoid exactly what you experienced.
Somewhere I read that the recommended tune power is a maximum of 5 watts.
Once the autotuner has established a number of settings for each band, I found it will take only a second or two for the tuning process to complete.
I tend to agree with Jimmy, that the high power, even at 20w may have caused something to burn out.

73,
Rob WB2OMW

7009. Z-817H vs CAT Problem

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-11-08 14:12:57 UTC
From: david@...
Topic: 7009 Message: 7009

Greetings! I have a system that no longer seems to function correctly, and the behavior is directly related to the presence of the tuner.

Specifically, I have an FT-817ND connected to a Z-817H auto-tuner and SignaLink. I am using an FTDI usb CAT cable. Everything worked perfectly in the before time. I've double-checked the settings and the cable attachments. The problem that I am having is that the CAT cable functions when plugged directly into the radio (HRD and N3FJP can connect and communicate in both directions) but when I have the tuner in line, HRD reports that it can't connect because it has 'failed to read the frequency'. If I open N3FJP, I can send commands to the radio, but I can't read anything from it.

Again, everything was functional previously (though I haven't used any computer functions in a couple months as I have been mainly doing CW and SSB in the field). The rig is on external power and the tuner has a fresh set of copper tops. Any thoughts would be appreciated. Thanks.

Sounds to me that the DTR or RTS isn't functioning, or is being
blocked. Have you changed operating systems? For me, I have some USB
to COM adapters which will work with Windows XP but don't have a driver
for Windows 8.1. The manufacturer makes a newer version of the adapter
which will work with the later versions of Windows, but for now, I've
taken my Windows XP computer off of the WIFI connection, and manually
update the logging software.

I've routinely been tuning it with 65 watts (that's the power used for my amplifier). The manual on the AT-600 Pro II says this:

"The AT-600Pro will not tune if the transmit power is over 150

watts, or if the transmit power exceeds 100 watts during high SWR conditions, in order to protect

the switching relays."

But it does recommend - if a rig doesn't have the ability to foldback at SWR to go no higher than 25 watts (although most, including mine, do foldback).

However, based on all these notes, I'll start reducing the tune power I use and will learn from this.

I did have to go up to win8.1 when the win7 computer went belly up, but:
1) The FTDI driver is good for win8.1, so it should work
2) I tested the system a few times after switching to 8 and it was
fine. It's just now stopped being fine.

Thanks for the responses folks, turns out it really doesn't matter, the AT-100ProII just takes care of business.

I did look in the manuals, either over my head or nothing pertaining to what the radio connector expects. This proII does indeed have a jack on the rear bottom right (facing the rear), just to the left of the power connector marked "RADIO" (not an RF connector).

Played with it a bit tonight, I think I am in love :-).

Tnx es 73, V.

No, I do have that driver update, but the chip still reports the proper
PID, and as I say, works fine when I take the tuner out of the loop.
They only thing I can figure is that maybe the radio to tuner cable has
gone belly up, and I've ordered a replacement.

From: Marty
Topic: 7002 Message: 7023

Hi Bill,
I have decided to sell the tuner. As you requested, you are getting first crack at it.
Now as far as pricing goes, this is what I found R&L values a working tuner at 175.00.
Obviously, I would not expect anything like that.
I am a believer in that if you treat people fairly, they will do the same.
Bottom line, make me a fair and reasonable offer and we will go from there. I have not been able to find out the cost of a individual relay, so I could price it out.
As far as shipping goes, 15.00 should cover it, if more I will eat it, if less, you will get the difference.
Think it over, no hurry. The tuner is not going anyplace.

Bought AT 100 PRO2 AUTOTUNER less than two years ago and the SWR on the tuner intermittently flashes to “over” when the freq is 14.070. When I take tuner off, the antenna is resonant and my Icom 7000 has a one to one. Tried a reset Func Ant and Tune and I get the same results. Interestingly enough, when I am on 7.040 I do not have that problem.

Thanks in advance,

Dan

7029. "OLD" (Original) Z-11 Power Ratings

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-11-17 07:54:57 UTC
From: k7hi.mm@...
Topic: 7029 Message: 7029

My Z-11 has the firmware upgrade and performs flawlessly. It's rated 30 Watts continuous and 60 watts intermittent. I always tune at 5 Watts (or less) and observe the "30 Watt continuous" rating.

On SSB voice, my FT-857D (100 Watt) is producing ONLY 15-20% "average power," (less than 30 Watts), typical for SSB voice service. So I don't see that running 100 Watts PEP into a matched antenna through the Z-11 would exceed "30 Watts continuous" limitation. Also, some current production LDG tuners, rated at 100 Watts+ PEP, are limited to 30 Watts on PSK, a nearly continuous duty mode.

Any comments or guidance on power limits and component/relay voltage ratings in the ORIGINAL Z-11 will be appreciated.

The tuner should work with your radio...

This seems to be the most common problem:

Are you using Antenna connector #1?

- Only antenna #1 is uses the external tuner.
- Antenna #2 will uses the internal tuner when the external tuner is connected.

With the external tuner connected, the radio should show "EXT" on ANT #1 and by-passes the internal tuner.

7037. Z-11Pro II Max Power into Mis-matched Load

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-11-19 23:40:23 UTC
From: pappaswa@...
Topic: 7037 Message: 7037

I am running a Z-11Pro II into a 36 ft doublet feed with 12 ft of ~300 Ohm ladder line off of a LDG 1:1 current balun that is screwed directly into the back of the tuner through a PL-259 double male adapter. My original intent was to use this on 20M and up, but found -- to my pleasent surprise -- that the tuner would match on 40M as well. At 40M the setup above is closer to 1/4 wave doublet which I know isn't terribly efficient. Do I run any risk of burning up to tuner in a set up like this? Said another way, if it finds a match will it operation safely to its specs, i.e. 100 W SSB and 30 W packet? I've already made a 40 M contact on SSB running a modest 20 W, so I know it is getting some amout of signal out.

Hi Neil,

The FT-450 has a nice option that lets you program the CS button for tuning an external tuner and/or amplifier.

I use this set up with an LDG Z11 pro tuner.. Works great.. press CS the radio switches to CW and puts out a 10 watt carrier. No special cable needs to be connected to the radio, only the coax.

You do not need a radio or brand specific tuner. Use a generic tuner that will work with any radio. You can use any auto tuner that uses RF sensing to tune. I like the Z11 pro as it has a wider tuning range than some other tuners. I have two of them and have not found anything I can't tune..

There is no real "reset" according to LDG. The tuner remembers the settings for each frequency until you hit your "tune" button, then it remembers that setting for that frequency for the next time. It just cascades through the settings and they are eventually over written as the memory fills.

Date: 2014-11-24 05:05:59 UTC
From: poppafred@...
Topic: 7046 Message: 7046

I have a seven year old LDG AT200Pro, original not the II. It's tuning a Hustler 9BTV vertical mainly, radio is an Icom IC7000.

I noticed the other day that I have been slowly increasing the power to make contacts. The SWR meter shows 50 watts out of the radio through the meter and into the tuner. I put an RF meter at the vertical and it showed only 25 watts was reaching the antenna! Suspecting the buried coax had been damaged by a mole or gopher so I pulled it all up and checked it from the vertical to the house. The outer skin (non-contaminating, direct bury coax) was damage free, not even a nick. The only other thing between the SWR meter and the antenna is the jumper between the meter and the tuner, about 15" of RG8X.

So, the question- Has anyone ever had an LDG tuner not pass all the power through to the coax and antenna?

I have always used the right SO239 for the vertical and, until now, have never had a problem.

I am scratching my head over this one.

How long is the coax? What kind is it? What is the SWR on the other side of the tuner, out to the antenna? Losing half your power is only 3 db, easily possible if the coax is lossy, long and SWR high.

If so, you might try a RT-100 which is a remote autotuner. The SWR on the coax from transmitter to antenna stays low, whatever the best match is, and higher only on the short run from the RT-100 to the feedpoint, usually very short.

On a G5RV I had, using a manual tuner, an expert figured the loss in the RG-8X coax to be 13 db, with an SWR from the tuner to the antenna approaching 60:1. No wonder I wasn't getting any replies! The 5 watts leaving the tuner evaporated to only about .05 watts at the feedpoint! But the transmitter was happy!

Fred,

Your Hustler (9BTV or should it be 6BTV?) vertical, if properly tuned, should have a minimal SWR somewhere on every band it is designed for. You should check your SWR on each band at the radio without a tuner. I have a 6BTV, which has a minimum SWR point on every band. On 40 and 80, it isn't as low and on 80 the bandwidth is very sharp. You may have damaged trap or 80 meter coil causing the antenna to be very high SWR, resulting in losses in your coax due to an extreme miss-match. You can also check your coax with a dummy load at the antenna end. You should have 1:1 at the radio with no tuner with the dummy load. You should only need the antenna tuner to lower the SWR at the band edges to keep the radio happy.

LDG tuners are great but miss-matched antennas can easily exceed the range of the tuner and even damage it. Check out that antenna.

The coax is 100' of low loss, non-contaminating, direct bury, the best the Wireman sold of its type. I figured that the best he had was the only way to go for a once in a lifetime setup. Now that I am on disability, I figured it would have to last me a long time so I didn't want to go cheap.

Thanks, Phil,

No, it's a Hustler 9BTV. I put every add-on that DX Engineering sells on it so it now covers everything from 10m to 80m, including 60m. Works well, too! I actually used it to make a contact on Australia's west coast, 10,000 miles+ away once. Ground mounted, 58 radials of 4 different lengths. I'm proud of it.

To be honest, I had not considered a changing SWR as the culprit. I've had a mole problem for a couple of years and was most concerned about something chewing into it. After I pulled the coax up and found its skin pristine and intact, I have considered getting some conduit to run it through when I rebury it next spring.

The last time I checked the swr with my MFJ analyzer, it was fine. That was back in the spring though. I used Penetrox on all the joints of the vertical and that may need to be cleaned off and refreshed. It is several years old, after all.

My concern was that the relays in the AT200Pro needed to be cleaned or something but I don't know a lot about the internal workings of the auto-tuner. I know it rattles up a storm every time I hit "tune"!

A remote tuner is not an option on my income anymore so I have to figure this out and make it work.

Thanks, everyone, for the tips. I'll keep you all up to speed on what I figure out .

You did not mention it was being powered by a switching power supply. Try a linear one.

Snap on RF chokes can be possibly still be purchased at Radio Shack. If not try The RF Connection or your favorite radio store.

Most any change, regardless of whether we humans think it is "minor" can upset the balance of RF/RFI in the shack.

Some of the things to consider:

1. Do you have a short, direct, ground to all components in your shack? If not, changing the power supply, with differing lengths of connecting cables, can certainly change the balance of RF/RF feedback getting into the matching unit.

2. What "quality" of coax and coaxial cables are your using to connect between the rig and the tuner? My friends who run contest grade stations, say that there are UHF connectors and then there are good UHF connectors. And, some of them say that "N" connectors are the only "sure" way to ensure that the RF stays inside the Coax and none goes astray. I'm lucky, in that I haven't had to bother with "good" vs "whatever radio shack or what is in my junque box" when connecting things in my shack, but my friends say I'm very lucky.

With a computer being inside the LDG tuner, and possibility of RF getting into it from the power wiring to it, the control cable between the rig and the tuner, and "leaky" connections at the UHF connectors or even from incompletely shielded coax, there are many, may avenues for the computer inside the tuner to "go possessed."

Do you belong to a local club? There probably are some "olde salts" there who would be glad to be your "Elmer" to look over what you have and offer advice. If not, perhaps a peek inside the ARRL Handbook or one of ARRL's books about assembling a station might be helpful.

Now, since this advice is offered "from afar", I'd suggest you try a few "clamp on" ferrite chokes. Someone else will have to give you a specific part number, but these chokes open up so you can place them over a power wire or a coax cable or a control cable. It might be overkill, but using one or more at each end of each power cable, AC cable, control cable, near the rig and near the tuner "should" solve the problem. It might be overkill, but, not knowing your setup, that "should" solve the problem.

Best to you and yours for Thanksgiving

How old is your tuner?

What happens when you run low power, like 3 to 5 watts? If it runs OK
at QRP power levels, that could be an indication that RF is getting into
the system with one or more of the wires which are connected to it.

Have you tried running it without a control cable from the rig - i.e.
use the "tune" push button on the tuner and disconnecting the cable from
the rig to the tuner? If it works this way, seems like RF is getting
into the rig from one of the wires inside this cable.

Have you reported the results of all of this experimenting to LDG?

They've gone overboard for me.

Hi John,

I am using the KT-100 here with a Kenwood TK-90 mainly but I have also used it with a TS-480SAT. It is basically a plug and play AATU solution. It provides excellent performance with 4 different HF antenna types attached to the Alpha Delta switch box. It runs on the TK-90 when in use as an ALE hardware radio 24/7 when the TS-480SAT is not running under software defined ALE control. So that KT-100 gets a lot of use in ALE, even in manual mode each time you change the channel the TK-90 tunes automatically and never fails to do so fast I might add.

I was having a challenge in using the TS-480SAT internal tuner with one antenna on 6 meters so that was when I first used the KT-100 with it and found it to tune that antenna, a Shakesphere 383 Marine whip FB on that part of 6 meters where it was not resonating. I had to add a pair of quarter way radials to get the TS-480SAT internal tuner to handle the antenna on 6m. At 6m the 393 whip is like a 5/8 over 5/8 antenna vertical and often an advantage over the loop depending on the DX signal angle.

I have many years of experience now with AATU's beginning with radio internal units and then external. The internal units for years were very limiting, my new TS-930S in the 80's offered an internal ATU option, awful performer that was by the way.

First your radio, P.S. and AATU must have a good earth ground where also between the equipments with an A.C. volt meter you do not detect and difference of potential.

I have found that regardless of the make/model, the problem if any is always related to RF getting into the units processor, either on the D.C. power line or coax shield and in really bad situations the case if its not a metal case or if the fit tolerance leaves a gap for entry. The use of all coax balanced transmission line antenna systems is the most challenging in dealing with common mode current issues. That 393 antenna is fed in that manor instead of having the AATU at the antenna feedpoint, there is a common mode choke using a 4 inch core there to decouple it from the coax though.

Most of the time a snap on toroid ferrite core made of HF material on the D.C. line and or coax line will suffice, but you often have no idea what material is being used with those if not stated However in more stubborn cases you need to use a solid type 73 or 77 ferrite material larger diameter donut core and wrap the leads around it to create a common mode choke.

The best of luck in resolving your issue in a timely manor.

/s/ Steve, N2CKH

Sounds like you have done well to isolate the problem and it is probably in the tuner. You might send it back to LDG for testing and repair. They do have great costumer service on repairs. Sometimes it takes a bit of time, however, if you have a manual to use in the meantime, you will only be out the shipping expense.

Subject: [LDG-auto-tuners] LDG KT100 THAT IS POSSEESED

I EMAILED LDG ABOUT A ISSUE WITH A KT100 TUNER AND A TS50S HF RIG.THE RESPONSE WAS TO PUT RF CHOKES ON RADIO POWER LEAD AND TUNER INTERFACE CABLE????? WHAT TYPE AND HOW MANY?THEY DID NOT EXPLAIN THE PROBLEM TO ME VERY WELL OTHER THAN I WAS GETTING RF INTO THE CONTROL UNIT.THE ONLY CHANGES TO MY STATION WERE A NEW SWITCHING POWER SUPPLY.CAN THIS BE THE CAUSE OF THE RF.I NEVER HAD AN ISSUE BEFORE WITH THE ASTRON RS 25 LINEAR POWER SUPPLY.IM A NEWBIE TO THE GROUP AND ANY HELP WOULD BE APPRECIATED 73S TO ALL JOHN/KC5ODT

Vertical is a modified HyGain AV-18VS. Took off loading coil at base.
Added 3 foot extension and top hat of 4 wites 2 foot each making an X.
Tune it with an LDG RT-100 autotuner at the base of the antenna. The
autotuner gives me essentailly 1:1 SWR on all bands 80-6. I keep power low
on 80 since losses in the tuner are bigger,

I do a lot of digital, mostly JT65, and have worked :"all over the planet"
: Australia, New Caledonia, Japan (on 40 M), S. Africa with 5-10 watts from
my FL QTH.

If HOA would let me I'd put in more radials.

Hello John,

The test with another type of tuner adds very little merit to the issue as you have described it. It still sounds like poor or inadequate grounding in the DC section of your station.

As we discussed externally to this group, follow the recommended procedures for returning the unit for a checkout.

7064. re: KT-100 and TK-90 on ALE

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2014-11-26 17:45:56 UTC
From: N2CKH
Topic: 7049 Message: 7064

Hello All,

I had a few requests for an idea of how fast the KT-100 works for ALE
so here is a short video of the KT-100 in ALE Sounding operation with
the TK-90 controlling it.

<http://www.n2ckh.com/MARS_ALE_FORUM/MOV04402.MPG>www.n2ckh.com/MARS_ALE_FORUM/MOV04402.MP
G

In the video you will see the radio scanning along and hit channel 13
then jump to channel 12 for the next Sounding event, check for
channel occupancy and if clear it will make the sounding
transmission. This repeats until all channels have been Sounded on.
You sill see the KT-100 commanded to tune at lower power and at a
good tune it will then go to high power for the Sounding. The
duration of the sounding is based on the number of channels, in my
operation in the this video it is much longer than on the HAM bands
as many more channels are being used in my MARS and SHARES operation
with the radio.

ALE requires a really fast ATU that can tune an antenna regardless of
its potentially changing characteristics over the MF/HF spectrum
quickly. There are aspects to ALE where even fast response is
required than for Sounding and AQC-ALE requires faster timing than 2G
ALE. The KT-100 fits that need and is a perfect match for the Kenwood
TK-90 which is becoming very popular in MARS for those who need or
want and can afford a hardware radio solution.

I have been using the AT-200PC for many years now with my MARS-ALE
software which has the added advantage of no RF needed for tuning as
the software tells the ATU the frequency for TX and tunes without RF.
The one that I have had in continuous use since it hit the market was
recently lightening damaged over the power line along with the radio
and the computer, one of the chances we take with 24/7 operation.

By the way, the flashing envelope on the radio display when not in TX
alerts me that I have mail in the form of AMD messages waiting to be
read. I have been using the ALE radio a lot lately instead of
MARS-ALE as I am planning out the design of a BeagleBone Black based
ALE modem/controller and I am subjecting myself to the suffering of
hardware ALE use vs the user friendly MARS-ALE/PC-ALE experience to
aid in making BBB-ALE a lot more user friendly than a standard ALE radio.

Anyone can feel free to email direct for any additional information.

/s/ Steve, N2CKH

Topic: 7067 Message: 7067

Hi All.

I'm trying to make a Pc interface for my LDG AT-600 Pro II, so I'm able to control it from a pc,
I have a RS232 to TTL converter which I know works, but when I sned the ASCII command via. hyper terminal, the tuner doesn't react. I know that I by mistake have made a short between the 12 volt and RX line in the 4 pin mini din connector, But I'm unsure if this has destroyed something in the tuner. If i measure on the 4 pin mini din connector I have constantly 5 volt on RX pin and TX pin, and I'm not sure if this is correct.
Could I have one of you which have one of the above tuners, try to measure on the 4 pin mini din connector and post the result. It is pin 3 and 4 the two upper pins. I have uploaded a pdf file in files section, which describe the interface and ASCII codes for control it.

Thank you in advance.

Kim / OZ9KL

Hello my name is Matt. I recently purchased a z100 plus for use with my yaesu 857d and my resonant 40m wire dipole. I'm using the y-acc interface cable. When I do a standard tune or a full tune it goes through the standard procedure but the green light never stays on. It never finds a good match. My swr meter is showing a 1.7 to 1 swr on 40. The tuner won't tune on any band. Any help would be greatly appreciated. Thank you.

Something like 90% or so of all the troubles I have ever had with antennas
and feed lines came from poor connections and/or bad coax. Before starting
to rip everything apart, it would pay to test the feed line and connectors,
for shorts, opens, loss, etc.

If you have or can get an antenna analyzer that would be good. Look to see
if you have anything like a normal SWR curve through the 40M band. Put a
dummy load at the far end, and a watt meter near the transmitter, take
readings, then put it out at the dummy load, see if the loss makes sense.

That's where I would start.

have you changed menu 20...on the radio to TUNER...and menu 85 tuner/ atas OFF..
turn the radio off..re=connect the tuner to the radio...then turn the radio back on..make sure the acc cable is in the right port not in the red jack at the back of the radio...I have a 857,897d with the same tuner....

Neil,

The green light does not stay on. When the tuner tunes the light will indicate the SWR at the end of the tuning cycle, then go out. It will not come back on until you re-tune.

The "Z" in the Z-100 stands for zero power consumption when not tuning. So the tuner draws no power until you ask it to tune again.

Hi Kim,

For the best operation always send your command packet to the tuner
with a header consisting of a Null and Carriage Return as HEX bytes
along with the command in ASCII and terminated with a Carriage return
in HEX. For example here is a 4 byte packet to toggle antenna ports
where you need to interpret the response from the ATU to know if its
ANT 1 or 2 that results and then perhaps send the packet again to get
the desired port.:

00h 0Dh A ODh

This is the approach that I developed for MARS-ALE and it never fails
to command the ATU models that support the meter port protocol.

Good luck.

Hi Jim,

Just wanted to say Hi, and reinforce what you said. I installed several antennas when I retired and got back into ham radio with a vengeance – new rig, amp, antennas, et al. Having been licensed since 1955 and having been a commercial radio engineer, I knew the importance of weatherproofing the feedline connections. I used several rolls on Scotch 88 tape wrapping the six connections.

Within a couple of years I noticed my SWR readings changing. After checking the suspect runs as you described (dummy load and antenna analyzer), I finally lowered it to the ground and cut off all the tape. The PL-259 showed a dull appearance (light corrosion). I cut the PL off and found wet coax. After cutting off about a foot, I found good, clean, dry coax.

The lesson learned was that tape alone is not sufficient it a warm, rainy climate. I now use pliers to tighten the connectors, a “liquid tape” to paint about 6” of the coax and connectors, and then the “88” tape.

After 5 more years, NO FAILURES. It does not hurt to over-do preventative measures; but, it does hurt to not do enough…! Tape – liquid and regular – is cheap in the long run. BTW, I run 1kW with a LDG 1000.

Very 73 es TNX for the good post.

Hi Steve.

I got confirmed from LDG, that there should be 5 volts on Rx and Tx, so my tuner works okay.
By sending the HEX commands it is also working now, so thank you very much for guiding me in the right direction.
According to the manual the command "P" is for bypassing the tuner (Passthru) , but this doesn't work correct for me. When my tuner is in bypass mode, the "P" command brings it on, and I can't bring it back to bypass with the "P" command. Do you know if the command is correct ?
Do you have other commands not listed in the manual ?
What is the MARS-ALE project ?

Thank you in advance.

Date: 2014-12-22 09:40:36 UTC
From: haydenph91@...
Topic: 7086 Message: 7086

Hi All,
I've just acquired an IT-100 tuner and hooked it up to my IC7000.

Antenna in, connect to rig, simple.

I then run a full tune on 6M. My antenna is 1:1 on 50.1MHz. So as a test I do a full tune on 50.2MHz. Best match found is more than >2:1?? What gives?

Tuning seems better on 10M. I've only tested on those two bands and yet to test on a dummy load.

I like to use FM on 10M and 6M and evidently didn't read the power specs properly either. 30W maximum on FM :(.

Regardless of what the specs say, I have found that LDG auto-tuners don't handle 6 meters very well. If your antenna is 1:1 on 6, I would advise to bypass your tuner for 6. By this, I mean completely bypass the tuner, not just use the bypass function of the tuner.

73,

Ken, KJ9B

Topic: 7086 Message: 7089

Ken might have his finger on the pulse here. I have an LDG AT-1000ProII and a LDG Z-11ProII. The AT-1000ProII will not tune my multiband beam which measures between 2.0 VSWR and 3.0 VSWR from 50.1 mhz to 53.5 mhz measured with my MFJ-259B. The Z-11ProII will tune the same beam as will the Yaesu FT-450D's internal tuner from 50.1 thru 53.5 without batting an eye. I don't give the lack of ability on 6 meters with the AT-1000ProII much thought since I don't have a linear for that band and it is only spec'd for 250 watts on 6 meters so an amp isn't very useful. The AT-1000ProII works nicely on all other bands though.

Subject: RE: [LDG-auto-tuners] Issue with IT-100 tuner

Regardless of what the specs say, I have found that LDG auto-tuners don't handle 6 meters very well. If your antenna is 1:1 on 6, I would advise to bypass your tuner for 6. By this, I mean completely bypass the tuner, not just use the bypass function of the tuner.

Subject: [LDG-auto-tuners] Issue with IT-100 tuner

Hi All,

I've just acquired an IT-100 tuner and hooked it up to my IC7000.

Antenna in, connect to rig, simple.

I then run a full tune on 6M. My antenna is 1:1 on 50.1MHz. So as a test I do a full tune on 50.2MHz. Best match found is more than >2:1?? What gives?

Tuning seems better on 10M. I've only tested on those two bands and yet to test on a dummy load.

I like to use FM on 10M and 6M and evidently didn't read the power specs properly either. 30W maximum on FM :(.

Regards

OK thank you for comments.

I tried using the bypass function of the tuner and the SWR did not change, still above >2:1.

So taking it out completely is the option, although inconvenient.

The SWR curve of the antenna is irrelevant here. It is a 6M 2 element Moxon antenna. R is 52 ohms and X is 0 at 50.1MHz.

50.2 is slightly higher R and a few X.

From: steve.lenaghan@...
Topic: 7091 Message: 7091

I have a FT897D feeding a AT-100ProII into a 20/40 shortened antenna. At this location it is hung 15' above the peak of wooden bungalow. On 28146 KHz I get an over range error on the power LED. If I manually reduce the power to 80 W on the radio (option 75) I display 100 W on the LED. At home I normally use my radio on a 135' OCF and do not see this action.

The antenna here is a deployment version and I haven't used it with this combination before. Grounds are good and the tuner and radio are bonded.

Do I really have more power on 10 M or is the tuner hallucinating?

Steve VE5SR/W4

7092. Kt-100 with a Icom ic-7100

Hi All! I have a Yaesu FT-897 with an older AT-897. Note that this is NOT the AT-897 PLUS. I just installed a mobile antenna--an Alpha Moto--and cannot get the antenna to match. I have a good ground, although the original unit does not have a ground lug. It clicks and clatters, but the SWR does not change. The SWR is the same with and without the tuner activated, by the way, around 4 to 5.
Steve at Alpha Antennas said the newer PLUS unit would likely work fine, but I wonder if the PLUS unit is the best choice. Would the YT-100 be better? Specs look about the same. Is it worth sending my original unit back for repair/refurbishment?
Any input you give will be gratefully appreciated...
Bryan S.

Try new coax, and be sure the ground connection is actually connected to other parts of the body of the automobile.

Also, if you have a way to do it, try a 100 or 200 ohm resistor as a dummy load - or two, three, or more 50 ohm dummy loads in series, and see if they can be matched with your current setup. That would determine if the tuner is actually working. With a mobile antenna, the SWR can be waaayyyyy out of range for tuning with most any tuner.

I have one of the orignal LDG Z-100's - I bought it from a friend who had set it in the back window of his pickup. It got so hot the plastic box was warped. He didn't want to buy a new box - which I found would cost about $8 plus shipping - so I got it from him for a pittance. It has worked flawlessly for 3 years. Don't know the original manufacurting date, I've never looked for a date on the Printed Circuit board, and the manual on line does not have a copyright date. I suspect it's at least 10 years old because the ARRL's review in QST is dated May 2004. Once or twice I've exceeded their recommended 10 watts maximum for tuning, with no adverse effects. I try very hard to use between 3 and 5 watts for tuning/

As Timex is wont to say, LDG Takes a Licking and keeps on "maching."

72/73 de n8xx Hg

p.s. I have no financial interest in LDG Electronics.

All of those listed. And, add a 4/1 Voltage Balun.

I have the same setup with a LDG Z-100. On some bands the 4/1 voltage balun works best. On other bands the 1/1 current balun works best. Sometimes if it's raining, or ice covers the antenna and feedline, the alternate works better. LDG makes a "200 watt PEP 4/1 voltage balun", which works fine for transforming resistive loads, or moderately reactive loads of up to 200 watts PEP SSB or 100 watts CW or 50 watts RTTY. With highly reactive loads, of whatever strange impedance a "lash up" on Field provides, we've burned up a couple "200 watt" baluns running 100 watts CW. They also make a "200 watt PEP 1/1 current balun" with the same caveat on power handling.

What works in your configuration is dependent on the length of the dipole, how close to earth and other objects it is, and the length of the feedline. Computer analysis helps, but the pudding is in the proof (or converse).

Hi Phillip,

There is no mention of the feedline used. Most multi-band dipoles use 450-Ohm ladder-line (also called window line). The balun would be a 9:1. Rather than buying a passel of different $50+ baluns, consider going online to “The Wireman” (Google it) and buy either the kit or his ready-to-use version. They can be rewound to any configuration. You can call them and get their advice, too. They are very trustworthy and dependable. It’s a good way to start. His baluns will run a kW PtP, less on CW and RTTY.

73, Bill – K4IZE

PS: Your planned tuner may already have a balun depending on the model.

I agree with an earlier poster that to make this decision the length of the dipole and height above ground is an important consideration.

I've used a "Carolina Windom" (Google it) antenna for many years and find it amazing vs the G5RV that was used prior. The Windom has a vertical element, balun and a decoupling choke and can be fed with coax.

Merry Christmas,

Craig

Yup. See
http://f1frv.free.fr/main3c_Baluns_fichiers/A_Better_Antenna_Balun_ZS1AN.pdf
http://f1frv.free.fr/main3c_Baluns_fichiers/A_Better_Antenna_Balun_ZS1AN.pdf

ZS1AN added a 4:1 Balun after a 1:1 Balun to improve the balance at both high and low impedance. It should go without saying we need large cores that won't overheat and be ruined running high power into a high SWR.

I remember melting the case on a "100 watt" Balun at Field Day. Heh!

Merry Christmas, Craig, We are basically answering a question with no facts to go on. I think they call it “guessing”…! Unless he has an analyzer or EZNEC, guessing is all anyone can do. As you point out, height, slope, support mechanism, near objects, wire diameter, feedline, etc, etc. all play a part. My purpose was to simply help answer the question about baluns. It pains me to think about buying several to get one that works.

No need to Google “Windom”, Designing and building antennas is a favorite part of ham radio for me – DX is another.

Bill,

The Windom antenna works well for me based on practical experience, many others prior, within on air experience less so. Maybe the Windom has loss (great SWR) and is not a good one. In my experience it has good TX/RX performance.

Tell that to Thomas Alva Edison. It has been called, since his era, the "Edisonian Approach" to solving problems. You make a guess, preferably an educated guess, if it works, fine, you're done. If it has problems, you try another couple things. If one of the other things gets you closer, or solves the problem, you know you're going in the right direction.

My opinion is that all too many folks don't have practical experience with what works and what doesn't work, because they're afraid to try without exhaustive study. They study a problem to death, try the one answer some "magical computer programme provides" and if it doesn't work they're dumbfounded and don't try anything else.

With the above statements, I case my rest, and will continue following Edison.

And then there's the "Allen-Bradley"method of circuit design; put an Allen-Bradley (tm) potentiometer of ABOUT the right value (.1 to 10X what might be needed) everywhere a resistor appears in the schematic of the stage being tweaked, and then adjust them until things work as required. A 'scope helps.

Topic: 7105 Message: 7105

I just purchased a LDG YT-1200 last week from HRO for my Yaesu FT-450D. All seems to work but I am not sure if the "2000 memory" stores my preset tunes. It seems like I have to re-tune every time I switch from band to band, memory-channel to memorychannel, etc. even if it is the same exact frequency I already tuned at. I have tuned, re-tuned on the same exact band, mode and frequency more than I can count.So I did some testing. I chose 3 frequencies on 40m (7.125, 7.200, and 7.300). I tuned it to each exact frequency then went back 2 frequencies before. It can only remember the last frequency it was tuned at but not any other frequency before that.So if I press the Tune button until the LED lights up, the SWR will shoot back up and it will go through the ~20 second full tuning cycle all over again.

I am well aware of the 3 different ways of pressing the Tune button (momentary, 1-3 sec, and the until the LED turns off). I have used all 3 states but for some reason it does not store any of the frequency I have already tuned at.

Is this normal or defective?

I have an Icom IC-7200 with the AT-1000ProII tuner and duplicated your test. On my tuner, it 'remembered' the proper tuning settings on each frequency, no matter what sequence I chose, no matter how often I did it. Based on my test, I would think that you might have a problem.

I have found, personally, that the gang at LDG will go above and beyond to fix a problem so it might be worth while firing off an email to Dwight.

Try just transmitting at low power when you return to a previously-tuned frequency. Don't press the tune button at all. In a fraction of a second the tuner should measure the new frequency and set the relays back to the memorized tuning solution for that frequency. If that happens the tuner memories are working and I would suspect a communication problem between the tuner and your FT-450D. Re-check the menu settings on your FT-450D.

Yes John, it does. I tried what you said by setting the RF Out to 10 watts. I went back to the frequency I have tuned already and transmitted. I did not hear the Tuner reacting and was reading SWR higher than 2:1 from the radio. Only after I had to press the Tune button again that the SWR went down to 1;1.

It is just annoying I have to tune every time I switch from one memory to another or from band to band, or even frequencies within the band. I always thought maybe I was not on the same exact frequency when LDG "stored" the setting. But my 20 saved memories in my radio is always the same and the test I did confirms it.

I sometimes forget pressing the Tune button until my radio registers 3+:1 SWR or it just beeps when its SWR is way over. Or sometimes switching bands my noise level just disappears and comes back only if I tune it again to the same frequency in the band I last left at and already did a a full tuning cycle.

I decided to try again with different bands and using the same frequency each time on the different bands...eg, 10M = 28.040, 15M = 21.035, 20M = 14.040 and the 3 frequencies on 40M. I tried them in different sequences and in each and every attempt, my tuner 'recalled' the correct settings. I don't know about the YT line but I would say that my tuner is working up to par.

Hope this helps.

I have a ldg at-600pro II. I am having trouble getting it to tune my
Carolina Windom 80 meter dipole.
Some bands the tuner has no problems with but other bands like 10 meters
it will not tune around 28.120.
The Ldg will not tune the 160 band at all, but the Icom will. This tuner
as problems somewhere on each band. The thing i don't understand is
that I have a Icom 746 pro with built in
tuner and it tunes my Carolina Windomon every band with no problems.
Why is it that the internal tuner which is not as good as the ldg doing
a better job?
Does anybody have any ideas, please respond.
Thanks,
Tom W4TRM

An old Icom AH-2A could match a foot of wire -- at the cost of enough circulating current to burn through a too-narrow trace on the PWB. Really,SWR limits on tuners are to keep this sort of thing from happening; that, arcing, and burning relay contacts and the like.

Experimenting, I was able to get a match with the Icom tuner with a Hustler center-loaded antenna on a number of bands; with the 80 meter coil, for example, I could tune the portion below the coil on 40 -- but the CB-style ball mount I was using arced over and caught fire while I was driving. Luckily, it went out when the RF was removed!

The AH2 was designed to match an 11 foot whip (on a SUBSTANTIAL insulator) from 80-10 meters, but results on 80 were abysmal, and only a little better on 40. 10 MHz and up was better and even quite good when I put the whip on the car roof. There is no substitute for size, and the LDG tuners, sensibly limited to sane operational regions, won't do any better.

Since you know the frequencies to be scanned, you might be able to parallel multiple antennas, with 50 Ohm bandpass filters andlaoding coilils in the few lower-HF channels the tuner needs help on. I've driven around with a bunch of antennas on my car and one CB operator, when his receiver recovered from my CQ on 10 CW a foot from HIS antenna, was heard warning truckers ahead to watch out for a little red car. "The mother ship has landed." Heh!

You might use a bumper to bumper whip, NVIS style, 20+ feet long, to make the lower frequencies more usable. It won't eliminate the size problem, but it might do well enough on a few more of the lower frequency channels. it might not; I could do that with my AH2 but THAT was kamikaze tuning.

I am using a FT Meter with my FT-897D.
When it is reading the TX power I have found that the readings from it are not very linear.
When the TX power is about 50 watts it is reading 28 Watts, but at 100 Watts it is reading 90 Watts.
As far as I can see there is no way of correcting this.
Is this typical of a FT-897D or is mine faulty ?.

OK, to get this straight:
- is the radio in FM mode ?
- what is the power set in the radio menu ?
- what does the LDG meter show ? (I understand 28W)
- what does the external power meter show ? (I understand ~50W)

You could expect the Yaesu internal power meter (that sends info to the LDG meter) to be non-linear, after all the S-meter is useless (even though after calibration I could get some useful info out of my FT-897).

Razvan.

I have an FT-897D with AT897Plus.
I often do some SWL-ing and Broadcast Band DXing.
Is there any way to make the AT897+ match/tune an antenna in this application, without going into Transmit mode (which I don't think the 897 would do outside of amateur bands)?
If not, I assume I'd have to bypass the AT897+ and use a manually operated tuner.

Topic: 7127 Message: 7128

Hi Chuck, the FT-897D is capable of all frequency transmit from 1.8 to 30MHz continuous with a simple modification. However, transmitting on non-ham frequencies is obviously illegal and is normally carried of for MARS/CAP type purposes or like me, to "future proof" against band changes that happen from time to time.

The AT-897 is also capable of continuous HF tuning however, it cannot match without a carrier being sent, so using to match for SWL purposes is not an option.

The LDG manual should have instructions for how to connect and use the tuner with a generic transceiver or transmitter. Also, look in the Kenwood manual for a menu setting that will set one of the PF (programmable function) buttons to transmit low-power CW. This is intended for convenience in SWR checking and tuner adjustment.

I don't know of an off-the-shelf product which will let you use the Kenwood trancsceiver's front panel AT button to trigger tuning unless you have the LDG model KT-100. I use my KT-100 regularly with my TS-480, but I have used it with my TS-590, and it is very convenient to use.

My generic comment on LDG tuners, based on forum comments and my experience with the KT-100, is that they are sensitive to RFI. I have installed big ferrite beads or toroid chokes (common mode filters) on all three cables connected to the KT-100, otherwise it sometimes has problems making a good match.

I have an AT-100-pro that has worked great for years with my Icom 706. When Cheapham discounted the YT-450 I bought one. It worked fine for about a week, then it locked the FT-950 in transmit and would not tune. I turned off everything and started again hoping it was just a fluke. After that pushing the tune button on the YT-450 did nothing. I have sent the YT-450 to LDG for repair. I hope they can solve the problem. It was fine while it worked so this is not a complaint. The antenna is a G5RV.

I could have just used the AT-100-pro on the FT-950 but I like a one button solution. So for now I'm using a manual tuner on the FT-950.

The FT-450 doesn't need a special tuner. One of the great features of the 450 is that you can program the C.S button as for tuning your external tuner (or amp). You can also set the power output for this, I used 10w.

All you need is a tuner that will tune when it senses a RF signal.. LDG, MFJ.. etc. (I use the LDG Z11 Pro) Press and hold the C.S button and the rig puts out a CW carrier as long as you press the button. Hold it until the tuner completes the cycle.

A benefit is you don't need a dedicated tuner that is tied to one radio. If you change radio you can still use your some tuner. All the info is in the manual... it is worth reading..

7139. AT100-ProII - memories per antenna?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-01-19 16:33:31 UTC
From: kevin@...
Topic: 7139 Message: 7139

I have two wire antennas, a fan dipole in the attic and an end fed that I run outside. I currently only have 1 current choke so I swap between the two antennas, only one is connected at a time. If I'm right, the AT100 has memories per antenna, is this correct? So if I'm swapping between 2 different antennas and only one is connected at a time, it would make sense to connect each to their own antenna input on the tuner and be consistent with with antenna I connect to which input on the tuner, would that make sense?

Thanks!
Kevin KK6DCT

Kevin KK6DCT
Kevin, your post caught my eye inasmuch as I am in a position where I
have downsized and my only option
is an end fed wire from my window to a balcony, both second floor. So
far no joy, could you please describe
your end fed antenna. I have a well used RT-11 LDG tuner but it's
matching characteristics are the same as yours. I also have
a 1:1 current balun. my problem is I have no ground so I have to rely on
a counterpoise, of sorts. Your wisdom with
your LDG tuner would be appreciated. Many thanks, Keith, VE3JKC.

Warren:
I have the same tuner and it memory tunes just fine. What power are you tuning at? Have you tried the manual memory tune as described on page 14 (near the bottom) with the 0.5 to 2.5 second button hold? I can run any test on my tuner that might get to the bottom of this.

Hi Keith - the end fed I'm using is the QSO King, sold on ebay by Maple Leaf Studio. I haven't had any problems matching it with the LDG tuner, although on most bands it has < 2:1 swr anyway, in most cases < 1.5 : 1. I sent my threshhold on the tuner to 1.5, on 40m, 15m and 10m the tuner clicks in and tunes within a couple of clicks. I'm not using a counterpoise, but the instructions for this antenna have a minimum recommended length of coax, I suspect because the coax is acting as the counterpoise.

I'm not sure what's inside the matching box used by the QSO King, but I don't have any complaints so far.

Brian,

Thanks for the response. I have a Flex-3000 set to tune at 10 watts. I have followed the procedure on page 14 for manual tuning but when the unit didn't seem to remember on it's own after several days I tried doing the manual tune followed by the memory store procedure at the bottom of page 18. Still when I change bands and return I have to manually tune each time.

My 200ProII would remember the tuning using basically the same procedure so I could memorize the antenna settings for all bands. I using a Cobra Ultralite antenna if that has any bearing. I really like having the large meter attached to the tuner which is the main reason I switched to it.

Am I doing something wrong or is there a different procedure to store the settings?

Warren:
Just one last clarification for my understanding: when you say manual tuning, are you referring to 'full tune'? The memory tune still requires you to push the tune button after changing bands or frequencies (unless you are set to fully automatic tuning and go ahead and transmit). Are we talking the same language?
If you are pushing the tune button for .5 to 2.5 seconds and it can't recall a previously stored tune, then it's probably defective.

Did the 200ProII work the same way?

Brian,

I switch to full auto and it seems to be working. The 200Pro worked either way so I was in memory tune so the tuner wouldn't go into a full scan which interrupts transmission.

At any rate it is working as expected now thanks for the help. I love these tuners.

Hi Kevin and thanks for the info. I had looked at that antenna before but as you say it seems to need a specific length of Co-Ax. My situation is having downsized from 2 wooded acres and lots of antennas, I am now in a second story condo-apartment and my feed point is at the window, so really no Co-Ax feed. Oh yes lots of restrictions. But thanks for the response. I have also purchased the LDG RT-100/RC-100 remote tuner and if I can sneak a hole in the wall I can use it. After 65 years in Ham Radio, anything is possible. Best 73, Keith, VE3JKC.

Just the case is similar to the one from Z-11Pro II, the insides are totally different - and they
seem to be using quality components. I'd say it's a very good thing there are other options out
there, it can only benefit the customers.

The origina design was published so the design is out there for public consumption. All they have to do is come up with the srouce code for a modern microcontroller. Granted they copied the casework from LDG, and the design is likely a copy, but really nothing can stop them.

Hi Steve,

Yes we know there is a built in tuner. The problem this tuner, like those in most other transceivers, is that it only can match antennae with a SWR up to 3:1 match (some where around that). It is good to touch up the match on a resonant antenna when you go away from the tuned frequency. It is more of an antenna tweaker. A lot of us would like to see a LDG type wide range tuner in our rigs . For some reason, the manufacturers just don't get it.

Some of us use antennae that have an SWR a lot higher than 3:1. My antennae system is not resonant on any amateur frequency. It is intentionally made this way for multi-band use with a tuner. External tuners like LDG have a much wider tuning range up 10:1 and work very well.

I run a 135' OCF which does a reasonable job on ham and CFARS frequencies but I expect the radiation pattern to be all over the place considering elevation and orientation. I reminded my customers all the time that an antenna tuner, fixed, mobile or airborne is only to make the radio happy with the antenna impedance. If you have a SWR of 3:1 at your radio you are losing 33% in reflected power. It gets worse http://www.arrl.org/files/file/Technology/tis/info/pdf/q1106037.pdf as you go higher in SWR. Then there is the quirk of line loss. The reflected power read at radio is actually lower than at the antenna. At VHF/UHF this can mimic a situation where apparent SWR is good and the antenna 150' up is actually open.

Having a tuner that will tune a bedspring or wet string is good for the radio but not for communications.

My suggestion. If the SWR is higher than you would like, consider rebuilding your antenna to something more efficient, if possible for your footprint. Military Sigs suggest building HF antennas for the lowest frequency needed and using harmonically related frequencies. Consider a T2FD

For various reasons, some of us do not have the space and/or option to put up a good antenna. (good by others standards) The LDG tuners work very well in these situation.

I've been playing radio for around 50 years and once had nice antennae, tower and beams. Now am retired, living in a senior housing unit. I'm happy to have what I have for antennae.. I'm on the air and having fun..

Despite the math and all the figures it is surprising to see just how well my compromise antennae work. I've worked the world, all with less that 100 watts and often even with a QRP rig. Today I had a nice long QSO with a chap in the US, on 15m, running 5w AM (IC-703).. into my home-brew vertical. It is is 25 ft long, about 10ft off the ground with 3 short radials.. fed with a LDG 4:1 Unun and of course a LDG tuner in the shack. My other antenna is 80ft long, fed in the center with about 15ft of 300 ohm twin-lead to a LDG 4:1 Balun, then coax into the shack and to the LDG tuner. (Z11Pro).

Tuners like the LDG have their place. It's nice to have the best for antennae but as I tell other hams all the time, put up what you can.. what fits your space and budget, use some kind of tuner even if you home-brew it out of junk. Get on the air and have fun.. Theory is great but it's what works in a situation that counts. There was a time when we had no SWR meters and no one knew about SWR.. thus we were not bother with it.. So how in the world did we ever manage to get on the air... Hi..

The tuner seems to work fine on 40 and 20 meters but when I use it on 17, 15 and 10 it appears that it gets a match but then fails to unkey the transmitter. It seems to work ok into a dummy load on the offending bands but not on my antenna. On those bands it indicates a good match and the relays stop after a few seconds - I let it go for a full 40 seconds but the transmitter never drops. The only way to get the transmitter to drop is to turn off the radio. The tuner works as advertised on 40 and 20 meters. Can anyone help? Thanks. Larrylane

It is not uncommon to see RF cause the xcvr to remain in xmit. A lot depends on the antenna design, the transmission line and most of all, your ground system. Perhaps if we had a more details about your setup, we could make some suggestions.

Have you tried those bands on a dummy load??

I have a home made end fed antenna I use a home made 9 to 1 unun. I believe the impedance at the fed end should be around 450 ohms
ie the need for a 9 to 1unun using a 1 to 1 may be your problem
why it won't tune. mine works great.
I could be wrong check out some end fed designs

7178. Frustrated with LDG Z11 Pro2

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-02-06 14:09:57 UTC
From: rmckee1957@...
Topic: 7178 Message: 7178

Recently I built an off center fed dipole for 80 thru 10 meter operation using a homebrew 4:1 dual core current balun. The antenna itself is working great except I cannot seem to get the swr below 2.3:1 on 80 meters and 2.2:1 on 17 meters, so I figured I would just get an LDG Z11 Pro 2 and us that to fine tune it with. Now, I hook up the tuner and on 80 meters it will start to tune and then stop at 2.1:1 swr - only drops it 2 points as measured on a digital swr meter. Then I use the manual tune mode using the C up button and get it down to a flat 1:1 swr. After a few minutes, it starts a new tuning sequence and stops on 2.1:1 again. Hit the C up button, drop it to 1:1 and a few minutes later it retunes to 2.1:1 again - UNREAL ! My Yaesu doesn't like anything over a 1.7:1 and cuts power back about a third with anything over that, so why does the Pro2 stop at 2.1:1 swr when the antenna is only 2.3:1 to begin with ? Is there a way to set it up so that it tunes lower than that and then doesn't retune every few minutes ? By checking the swr on the antenna direct, nothing is changing there, so why is the tuner retuning ? This is my third LDG product and had similar problems with every one of them. I'm ready to go back to a ladder line fed antenna and a manual tuner at this point ! If a tuner won't tune the antenna when its close to begin with, then its nothing more than a paper weight to me !

You would think that is not the case in a device that is designed to have RF running through it ? But I did add 10 ferrite beads to the coax to eliminate that problem when I built the antenna. Before I added them the swr would change slightly when touching the coax connector or from grounded to ungrounded. Now with the beads in place the swr stays steady and no RF detected on the shield with a field strength meter.

I would recommend putting an swr meter between the radio and the tuner - I don't trust the idiot lights on the tuner. Nothing wrong at all using an swr bridge between the tuner and the rig !

Better yet, turn off auto-tune so a cycle is started ONLY by the tune button. I do not have the same tuner, so pse excuse if this is not applicable.

You might also want to try it while bypassing the balun….

Try setting "Automatic Tuning SWR Threshold" page 18 in the manual.

Is it possibly the location of your equipment? Are you on the second or third floor of a building? Long ground connection? I've seen these things cause strange problems.

You didn't describe the physical layout of where the balun is in
relation to the dipole, and the location of the tuner.

But, my guess is that RF is getting into the tuner from the unbalanced
line from the Off Center feed. An OCF dipole IS, by definition, and
unbalanced load. There WILL be currents on the outside of the coax from
the feed point down to your balun. If your balun is at the center,
still the same, because you have unbalance in the antenna itself.

Try putting ferrite beads every place which you can. i.e., on the
outside of the coax coax and the power line to the tuner. and on the
outside of coax from the balun to the tuner, and, if there's coax from
the center of the OCF dipole to the balun, put some there. IF RF is
getting into the microprocessor it will be very erratic.

Note, I use 400 ohm (nominal) window (ladder) line feed, a LDG 4/1
voltage balun or a LDG 1/1 current balun depending on the band of
choice, to a center fed 80 meter dipole. I never have a problem with
my Z-100 tuner. Of course, it doesn't have an auto tune, I need to
punch a button to get it to tune. However, the SWR which my rig sees is
generally <1.5 to 1, after tuning the Z-100/ My rig doesn't care - it
will put out power at SWR=3/1 or even higher.

That works (generally) for modern day computers, but for the complex radios, it sometimes doesn't work.

But, I bought a very used LDG Z-100 for a song from a friend who had left it in the rear window of his pickup truck. The case was/is warped so bad that the clamshell won't fit. I taped it with electricians tape, put power to it, hooked it to my rig, and it works fine. I didn't bother downloading the manual until much later, just to see if there were any "tricks of the trade" which weren't obvious. The Z-100 has been working like a champ for over two years (maybe 3 years) now, both at home and in the field.

I even contacted LDG, have a source for their (obsolete) case, which is still in production at their supplier, but haven't gotten around to buying a new one.

I have the Z11 Pro and have had a similar problem. The tuner would tune down to 1:1 but would sometimes start retuning during a QSO. It would sometimes start turning if I keyed up a 2 meter handheld in the shack that wasn't even connected to it.

The workaround I used was to set the tuner so it only tunes when I hit the tune button it. It's an extra step, but it solved the problem.

I'm running a similar setup with a twinlead fed open loop with a 4:1 balun at the tuner.

Could someone give me a good explanation of "RF getting into the tuner"? I'm former Collins FSR, broadcast and avionics and worked on RF a lot more potent than this. Tuners are FULL of RF, its how things happen when you have all those wires and coils and stuff. The trick is keeping the RF inside the tuner except for the stuff you want at the antenna. If you try to tune into a load that is outside the capability of the tuner the excess reflected power will get back in. Remember that a tuner will not correct antenna SWR it will only attempt to match the radio to the load. So if someone here is a certified engineer with a specialty of this field I would love to hear a different explanation of what engineers in several organizations taught me.

I have put my Bird 43 in line with my AT-100ProII and found it to be accurate. I would put the meter after the tuner to give you an indication of what the real SWR is like between tuner and antenna. Remember the bridge is a 50 ohm impedance and if your antenna is significantly off there will be errors.

Steve VE5SR/W4

Steve:

When they mention RF getting into the tuner, they're referring to it getting into the logic and control circuits and causing functional problems. Some LDG tuners are more susceptible to that but mostly to RF coming in on the power and control connections. That happens when there's stray RF from the antenna or due to common-mode RF conducted back from the antenna on the outside of the coax.

While a tuner doesn't correct anything at the antenna, it certainly affects the amount of power that is radiated. It does this by, as you say, matching the impedance of the feed from the radio to the complex impedance presented to the tuner at its antenna connection. The net result of that is that all power from the radio, less I/R and dialectric losses in the tuner, is delivered to the antenna line at the output connector of the tuner. There may as a result be more voltage or current delivered to the antenna and somewhat out of phase, but it will be delivered and when a tuning solution is achieved, you will have the most power radiated.

The line from the tuner to the antenna will have additional loss due to the increased voltage and current that will periodically occur along the line (measured as SWR). That loss is not as much as many people think it is unless the SWR is extreme. There may also be additional losses at the antenna due to the higher current/voltage delivered to it or at various points on the antenna.

All of the losses mentioned above will depend on the quality of the conductors, insulators, and components, which is why smaller auto-tuners aren't as effective as the larger units. Also, the more extreme the solution, the more the losses.

Of course if the tuner is unable to achieve a solution to match an antenna at a particular frequency, power transfer from the transmitter to the line will be reduced. Whether you wish to look at that as an impedance mismatch or an effect of reflected power doesn't matter, the result is the same.

Chuck - N8DNX

The balun is a dual core 4:1 current balun at the feedpoint of the antenna itself - the 44' and 89' wires connect direct to it. The coax has 10 mix 43 beads on it where it connects to the balun. Before I put the beads on the coax, I was getting conflicting swr readings depending on the analyzer being grounded or not and could detect a small amount of RF on the coax shield with a field strength meter but none detected after the beads were added and the swr readings are now rock solid. Just for some reason have not been able to get the swr below 2.3:1 on 80 meters. As an experiment, I connected a 50 ohm dummy load to the LDG tuner and it goes direct into bypass as it should. Then I connected the 50 ohm dummy load to a manual tuner so I could vary the swr and connected the LDG to that. I used 1 foot jumpers between the tuners, the load, and the radio and adjusted the swr to 2.3:1 on the manual tuner and then triggered the LDG to tune it on 80 meters. After a few minutes the LDG started retuning the same way it did when connected to the antenna. So I put the LDG in bypass and adjust the swr on the manual tuner to 5:1 and let the LDG tune that. At a 5:1 swr, the LDG remains tuned, and I think somehow its getting confused when the swr is near 2:1 or a little above. Wierd stuff !

Chuck - N8DNX

Well, then how would it get in if you are not using control and power wires and using internal batteries ? But then I guess there are some very short power leads from the battery holders I installed. Maybe I should install some ferrite beads on the battery leads. But at any rate, you would think a tuner would be very well shielded since it is designed to have RF running through it.

I had an AT1000 pro with similar problems. Sent it back and was told there was nothing wrong with it. My antenna was not that far out of resonance with 1.5:1 at 20Mhz going to a 6.5:1 at 4Mhz. It is an end fed antenna which typically does have RF on the shield, however my old AT-11 tuned this antenna in seconds. I sold the AT1000 with the hope whoever got it had a more compatible antenna system.

Good luck. Jim

Hi Wayne,

A while back, I had a problem with my 600 Pro tuner and sent it back to them. It took about 5 weeks for them to get to it. They seem to be busy often with R&D and sales and I believe they have a relatively small staff, thus, I don't think they can devote a lot of time to answering emails. Having said all that, as stated in their website, they did contact me when the repair was done and shipped.

I don't believe that you have made a donation!

73,
Guy

Repair info is stated fairly clear in their website:
"Track your shipment back to us so you will know when we got it. Repairs can take as long as four weeks once we receive it, but are generally quicker. Unfortunately, we cannot provide status or updates while the unit is still in process. We will promptly contact you when your repair has been completed. We are unable to provide call-tags for repairs and do not cross ship units."

Five weeks may be because of the snow. I had a repair done awhile ago and it took some time then. They're a small company, so I can understand that sometimes they can be slow. My error was not to track the package I sent to them. If I had done that, I would have at least had the knowledge that it was in their hands and not on the side of Interstate I95 when it fell out of a UPS truck.

I think I remember them telling me that their repair tech is part time and does not do any email responses. Maybe I'm confusing them with someone else.

Wayne:

Have you been watching the news as of late. LDG is in MD. Very bad weather their several feet of snow. Maybe some people cannot make it to work. LDG has always been very good at service for me. Lets give them a break in this time of very bad weather. I live in WV with only about a foot of snow and have not seen mail delivery for a week.

Subject: [LDG-auto-tuners] Sent in for repairs

Has anyine sent their LDG tuner in for repairs I sent my LDG 1000 pro in about 5 weeks ago and have called and emailed with no response from ether attempt. I hope no one else is having this problem. Guess I donated my tuner to them.

This is my third LDG product and have had similar problems with all 3 of them. I also have an Icom AH-4 tuner and an SGC-237 and no problems with them on the same antenna. They tune to a lower swr and they stay tuned. The AH-4 is the best out of the bunch tuning most times to a 1.3:1 or lower.

I purchased a used cosmetically clean AT-1000pro. I connected it to my FT-2000 transceiver with an Ameritron ALS-600 amplifier.

It works as expected on CW, AM, RTTY (continuous carrier modes). However when I switch to SSB mode, the tuner goes crazy and has no RF output. This only happens on SSB mode, all bands, 80 - 10 meters.

Reading the LDG FAQ web page, they suggest adding RF chokes to the DC line. I added chokes to the DC cable from my Astron PS. the cable connecting to the FT-2000, and on both coax IN/OUT. The chokes do not appear to make any difference.

Has anyone else experience this type of issue? Again, it only looses its brains when I am transmitting on SSB, both in AUTO and MANUAL modes, all bands.

Try backing off the mic gain a little and see if that helps.

Hello,

It really still points to RF issues. Keep the tuner in the Semi (Manual) mode. Reduce RF power until the symptoms are gone. Then increase power until the issues start to appear. Then, start adding RF chokes to the places we recommend to see if the symptoms get better or not.

If they do get better, then you are on the right track. If they do not get better, it could be something else.

Make sure you have the correct antenna selected.

Also, please do not cross post as we asked.

Hello,

You are really comparing apples to oranges. The two units that you mentioned are specifically only made to tune random long wires at a remote distance.

If you had a dipole fed with coax, you could have great results with the LDG tuner located in the shack. But you can't do that with the long wire tuners in the shack.

Plus the units you mentioned cost quite a bit more than a basic desktop tuner. There is a great reason for that. The remote tuners you mentioned have a very wide tuning range (maybe 100:1 SWR). The LDG untis are around a 10:1 for tuning range, which we feel is the optimal tuning range for the cost of the unit.

We have never claimed that LDG units will tune every antenna ever made and often we recommend the units that you mentioned when the requirements makes sense to do so.

Jimmy,

You are correct. Monday was an observed holiday last week and we got over 10" of snow in an area that is not really prepared for snow travel. That pretty much put us a week behind.

We're still slightly behind today, but are catching up this week.

Unfortunately (maybe), we trade low cost repairs for no way to track repairs through the repair process. Any given unit that we have in the process will depend on the repair time of the units before them, so there is really no way to give time estimates,

We've looked a many repair processes over the years. We don't want the seriously long time (4 to 7 months) for repair as some companies provide and we don't want the seriously high price as some others (include a check for $250 with your return).

So we've tried to work on providing a minimal cost for about a four week turn around (once we receive it). Sometimes it goes a little longer, but most times it's much less.

Hello Dwayne,

Presently I am experimenting with the AH-4 tuner feeding a coax fed off center fed dipole. I made an adapter to go on the tuner so I could connect the coax to it and so far its tuning great. My LDG Z11 Pro2 will also tune this antenna but will not hold tune on 80 meters which is one of the 2 bands I actually need a tuner with this antenna. The LDG will only tune it down to a 2.1:1 on 80 and it only 2.3:1 without a tuner to begin with. I can use the manual tune mode on the Z11 and get it down to less than 1.3:1 but then it retunes on its own and stops again at 2.1:1 and this I just don't understand. But I'll keep playing with it until I figure it out and when the weather warms up and I can get outside and work on the antenna I may be able to get it set so I don't need a tuner at all. Time will tell.....

Dwayne Kincaid
LDG <snip>

Oh yeah, Dwayne,

My antenna is coax fed ! Its an 80 meter off center fed dipole that isn't that far off resonance to begin with - 2.3:1 swr on 80 meters and about 2.1:1 on 17 and those are the only bands I need a tuner for. The Z11 will only drop the the swr to 2.1:1 on 80 meters but I can use manual mode to drop it lower and then it retunes to 2.1:1 on its own. Haven't really had much time to play with it lately and I plan on trying turning off the auto tune to see if that works. I just don't understand why it stops tuning at 2.1:1 and doesn't tune lower ?

I have added RF chokes and more RF chokes, over 10. Same issue.

Works OK/solid up to 500 watts for all continuous modes (CW/AM/FM/DATA), however when I switch to SSB, the tuner cannot find correct setting, all LEDs flash, no RF output and turner locks up, Need to do DC power cycle to clear. This happens with a little as 10 watts SSB.

Maybe you can tweak the variable capacitor in the tuner (it is near the radio PL-259) to match what your radio or other meter sees and go from there. Just put a mark on it to set back to original it needed. If you try it, let us know how it works.

Hello,

It may depend on where you place the chokes. We see some RF getting in on the DC supply sometimes. Are you using a switching power supply? If yes, they are sometimes more susceptible to RF and ground loops. Try using a different power supply for the tuner.

Also turn off Auto mode. You don't want the tuner to accidental start tuning when there is 600 watts present.

Are you using the IC-2000? If yes, you may need to add chokes there.

I'm having a related problem with both of my AT-1000Pro and both of my old-style AT-1000 tuners (with a fifth being added to the mix in a few days courtesy of ebay, as of about an hour ago). They work fine until they don't, then they hang up tighter than a drum until I cycle power. All four of them do that at one time or another. I run from 600 to 900 watts SSB into each one. I have a little RF in the shack but not much... running four cheap computers here and they all seem happy as a clam with nary so much as a squiggly line across the monitor.

I have tried chokes (two or three each) on the power leads but that doesn't seem to do the trick... can't really tell if it helps but it might help a little.

I'm powering these (and all my other 12V gear) from a pair of large industrial batteries in the garage, through a couple of TGE Electronics 12V booster-regulators in the shack. Three of the four LDGs are driven by radios that plug into the wall (the fourth is an IC-746Pro that runs from the batteries) and the amps all plug into the wall, so it's not like I'm sagging the 12V power when transmitting.

For some reason pushing the tune button no longer has an effect on getting my 817 to go into transmit. It will tune if I key the radio independently but the tune button no longer initiates the process.

I've checked my cat rate and it's good at 38400. Changed AA batteries.

Any thoughts about what I'm missing?

Do you by any chance have a CAT62 USB cable attached to the tuner? I am having a similar issue with my FT817ND and 817H tuner. When the cable is connected to the tuner and the USB is not plugged into the computer, or the computer is turned off, the status light stays lit on the tuner and it just locks up. If I unplug the connector on the CAT cable all returns to normal. I think the circuitry in the cable confuses the tuner when it is not active???

I purchased the YT-1200 tuner for my Yaesu FTDX-3000. I have a G5RV antenna that I'm currently using with my FT-897D and the LDG AT-897 Plus Tuner which works great an tunes with no problem.

My first YT-1200 tuner worked for about two weeks and then it would tune and then just stop in AM mode and had to press the mike key to get it to stop transmitting. I disconnected the power in hopes for a reset. It started working for a day and then same issue. Then it would not even try to tune at all and just transmit in AM mode until I pressed the mike key.

I sent the tuner back to HRO and got another one. It worked for about two weeks and then the same problem. So I contacted LDG and sent the tuner back for repair. The technician was able to reproduce the problem and replaced the K8 relay.

I just received the tuner and hooked it up hoping that the problem was solved. Well it tuned two times and now the same issue. Press the tune button and goes to AM mode to tune and just sits there doing nothing.

Anyone have any suggestions? I just sent another email to support at LDG letting them know the same thing is happening.

I had a Z-817 which kept playing up and in the end the dealer changed the PCB on the FT-817 and it worked. Might not be the tuner, could be the radio or the cable at fault.

Have you double checked your settings on the radio:

Menu 039 - CAT Rate - 38,400
Menu 041 - CAT RTS - Enabled
Menu 040 - CAT Time out Timer - 100msec

Good luck,

Mike

I have been back through the messages and found this ancient posting, I have exactly the same issue with my IC-707 / Z-100 setup, can anyone tell me whether it was ever resolved please ?? According to the manual the IC-707 should only show 'thru' if the tuner cannot find a match and is in bypass mode
Greg vk5gj

"I have a Z100 connected to a IC-707, when I push the "tune" in the 707, it shows "CW" and "TUNE" just for a second, then switchs to the mode it was, and the Z100 starts to cycle, and usually ends up with a green SWR led, showing "THRU".

It seems all is normal, but the IC-707 shows THRU, almost all the time, except the one second when the 707 shows TUNE, even during the tuning cycle it shows THRU. TUNE it is only shown for one second after pushing. Anyway the tuner seems to work OK, as signal increase a lot after tuning cycle"

Hi,

First off, the thru/bypass mode is more likely to be activated if the antenna is is a match without the need of a tuner - i.e. it is resonant at the frequency you are on.

That said, I don't think this maybe your problem. I suspect you may not be holding the button down long enough. If you press and let go of the button quickly, the ATU goes into bypass mode. You need to press and hold for a second or so to get it to tune, or for 3-4 seconds to do a full tune to reset any memory tune at the frequency you are on.

Sorry if you are already doing that, in which case, have you taken SWR/impedance measurements when it has completed tuning. Also, have you ensured the antenna is between 6 and 800 ohms on the frequency you are tuning on? That is the range of the Z-100.

73 and good luck,

Mike

Mike,
The antenna is about 3:1 so that should put it within range of the tuner but not low enough to use the thru mode. The tuner works just fine when operated using the buttons on the tuner. My problem is with operation from the tune button on the txvr, when the button is pushed (no matter how long) the 'tune" legend flashes on for about half a second then thru comes on, the tuner operates and finds a match (usually about 1.2:1 but always lower than 1.5:1). The tuner does not go into bypass mode (the swr stays as tuned ie. 1-1.5:1) but "Thru" remains on at all times whilst the tuner interface cable is plugged in. I have also tried it using a 100 ohm dummy load which should be 2:1 (and reads as that on the swr meter) with the same result. This makes me think it is not the tuner or the antenna and maybe that the Z-100 does not fully emulate the Icom AH-3.
It's not a major worry as the tuner does do its job but I would like to get rid of the thru message that is there all the time - I saw the old posting and wondered if anyone had found a cure.

Good afternoon,

Last evening I let the smoke out of my month-old AT-1000 Proii. Internal inspection revealed a blown out 3200pf 500V silver mica cap. I am at a loss as to how this occurred, but the damage is obvious. I was operating on 40m using approximately 300 watts. Antenna and all other gear is still fine.

I am proficient with this type of repair and do not have a standby tuner. I do not want to sent it away for repairs.
Where can I source a replacement? The usual sources (DigiKey, Mouser) are proving unhelpful.

Thanks in advance.

The smoke sure helps everything electronic to work! I've seen it too many times myself.

Maybe someone on the list has a capacitor in the junk box, or maybe contact LDG and convince them you can to the repair yourself.

I'd also consider sweeping the antenna at the band of interest (or multiple bands) to see if there is a problem. If might be good to try on a calm and a windy day which might show a loose connection in the antenna system.

If you don't have an antenna analyzer, try legally transmitting at minimum power (maybe 10W with the driver), without a tuner, and identify a baseline SWR and if there are variations in the SWR with wind.

Please also post what kind of antenna you are using, how old it is, feedline and such which may help others on the list help you.

What kind of Amp are you using? Does it show any signs of oscillation?

73,

Craig

Try RF Parts, "www.rfparts.com". They have a 3300pf 500V Silver Mica.

What really surprises me is that the voltage rating is only 500 Volts. I would thought it would be 1000 or higher.

Frank,
AB2ZO

Thanks for all of the suggestions. The 3200pf value is uncommon, but I found a source on eBay and ordered a pair. Should be here in a few days.

I will endeavour to analyze my 40m wire dipole for any changes. It's certainly possible as it's been a tough winter. The amp is an AL-80B with a brand new RF Parts tube. Seems to work well on all bands.

My LDG YT1200 tuner purchased when released from HRO has gone out. Won't tune 10-20-17 or 15 meters any longer. Unplug cable and reinstalled, 3 different antenna, still won't tune these bands any longer.

Back to internal tuner and all bands tune up depending on antenna. Do I cantact HRO or LDG? I purchased it for the 2 year warranty.

I see people waiting months for repairs sometime on web.

Any suggestions or LDG if you on here help????

Assume you're using an FT-897 radio with this?

Do you have CAT selected (menu 20) and baud rate set at 4800bps (Menu 19) on the FT-897?

Are you connecting the ADMS CAT cable to the tuner and then the short jumper from the second CAT connector on the LDG 897Plus to the radio's CAT connector?

Does the tuner work if you connect only the AT-897Plus to the CAT connector on the radio?

Do the PC and the radio talk to each other if you just connect the PC/ADMS cable from the PC directly to the CAT connector on the radio?

When I switch from frequency to frequency on different bands, that I've already visited and presumably stored tuning on the AT-897Plus, do I have to press the button each time to re-tune? Or does the unit automatically tune?

I'm using WSPR4, which band-hops via CAT control of FT-897D, so was hoping an ATU would be able to sense the switch and re-tune - the app send a carrier signal each band switch.

Wayne,

It doesn't matter how small the problem is, they are all done in the order that we receive them. It would not be fair to the others ahead of you if we thought your issue was easier. What if someone had a difficult problem? Does everyone with an easier issue get to ahead of them? These are rhetorical questions, but it provides the information on how we process the units.

7248. FT-991 Menu settings for use of YT-1200 tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-03-28 19:37:08 UTC
From: joe@...
Topic: 7248 Message: 7248

I purchased an LDG YT-1200 autotuner when I pruchased my FT-991.
I am a member of NAVY MARS and operate on some rather odd frequencies
as a result.

The YT-1200 does an excellent job of tuning to these frequencies,
and I recommend it to anyone faced with a situation similar to mine.

Unfortunately, the LDG instructions did not cover setting the menu
options in the FT-991.

After following the Quick Set-up instructions for connecting the tuner
to the radio, by trial and error I came up with the following FT-991
Menu settings:

028 gps/rs232 rs232c
029 232c rate 38400bps
143 tuner select external

After setting these menu options, the YT-1200 works as described
in the LDG manual.

I hope this may be of help to anyone interested in using the tuner
with the FT-991.

It is good to remember that you only need to put out 10 watts of AM for it to tune. I use a AT-600 PRO with my 950 into a SB-200 into the tuner. A second of 10w AM, tune the 200, and as they say in UK, "Bob's yer uncle". Though not as versatile as my old Heath SA-2040, it is waaaay more convenient and lighting fast!

It seems to me there are two choices.

One, no balun, feed the antenna with twin lead, with a tuner in the shack, or use a remote autotuner at the feedpoint with coax into the shack, or

Two, put a balun at the feedpoint and run coax back to a tuner in the shack.

If the dipole is to be used on several bands, you might have a problem of very high SWR which means lots of loss on the coax run out to the antenna. Best to use twin lead or a remote autotuner in that case.

I try to avoid losses wherever I can, so mostly I want to use twin lead and avoid coax, or remote autotuners. I use a RT100/RC100 and a unun on a home brew vertical which gives me a very good match on the feedline, minimizing losses. Whether I lose more in the tuner and unun, nobody can say.

I'm in the process of putting up a horizontal loop, and the question is whether to run twin lead in to the shack to a tuner, or mount a tuner up on the mast, or run twin lead down to a more convenient mounting location for the tuner.

Depends. How are you feeding the dipole? What band or bands?
For example, I am using a 102 ft center fed with 450 ohm ladder line to a 4:1 balun in the shack and a very short piece of coax. Running a FT-950 into a SB-200 and a LDG AT-600PRO. Can tune 80 thru 6.

Also using an Eagle One on my awning, fed with 20 feet of coax. Tends to bypass on 40 and sometimes 15, but also makes a good signal.

IMHO don't try to feed an all band dipole with coax; losses will be high.

Look up G5RV, but remember that Varney said that when you could, it was better to have ladder line all the way to the shack.

John:

I guess it depends on whether the antenna is intended to be single-band or multi-band and how you want to feed it. If it's single-band you probably have several options for how to feed it. If it's multi-band, you might have an insulator in the center and feed both sides directly.

Some feed types are essentially a balun while some might require the addition of a balun to prevent common-mode current on the transmission line due to balance issues.

Tell us more about how the antenna you would like to build, what band or bands, and what you want it to do for you.

You should not NEED a tuner, but a 1 to 1 balun would be a good idea.

depending on the height above ground, the rotator may or may not be
needed. It's not a bad idea, though.

ill try to be a bit more specific this post

i am going to build an aluminum tubing dipole 15 meters 1/2 wave
i will feed it with 50 ohm coax, element will be isolated from the boom
the question is......
if i use a tuner will having balun at the antenna be
an advantage or a dis-advantage (or just not necessary)
(I may want to use the tuner to access 40 meters also)

john

IF you use a half wave antenna, cut for 15 meters, it will be about 7.5 meters or 22 feet tip to tip.

It should work fine on 15 meters, preferably with some sort of balun (typically a coil of coaxial cable right at the feed point).

However, it will be very, very, very short if you try to use it for 40 meters. You "probably" will have a hard time matching it to your rig. If the impeance matching device is at the transmitter end of the transmission line, you'll probably burn up a significant amount of RF due to SWR in the feed line. Generally, the shortest antenna length for a 40 meter dipole is about 44 feet long. I forget the details of why, except folks tell me that a radiator fed in the center should be at least 3/8 of a wavelength long, and 44 feet presents an "optimum" for a reason which escapes me.

Now, the alternative, a 20 meter (67 feet), or thereabouts dipole cut for 40 meters is 1/4 wave length on 40 meters. On 15 meters it is 3/4 wavelength, and a reasonably good match to 50 or 75 ohm coax, using the same balun as you'd use for 40 meters. It will have more directivity than a 1/4 wavelength antenna, broadside to the wire. The lobe will be compressed.

Of course, making a rotatable 67 foot dipole is considerably more difficult than one 1/3 the length. But if you want to use it for both 40 and 15 meters without needing a machine device . . . .

It will not work on 40; it's the other way around.
Make a 32 foot center fed with ladder line. Will work from 20 to 6.
Make one 102 feet long and will go 80 to 10.
Coax on any other than the resonant band will not work well.

7260. LDG RT/RC-100 Not Working?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-04-04 17:47:54 UTC
From: cbjesseeNH@...
Topic: 7260 Message: 7260

I put a LDG RT-100 in my coax feedline from a G5RV antenna, and connected the LDG RC-100 DC source between my feedline and transceiver, with a SWR/Power Meter in between them. Tuning up 25W on any band shows no change in SWR, suggesting the RT-100 is not functioning. The RT/RC-100 will not tune in automatic or manual modes. SWR measured is: 10m (4.54), 12m (6.35), 15m (7.35), 17m (6.84), 20m (3.49), 30m (7.05), 40m (10.3), 60m (12.4), 80m (14.9), 160m (59.5). The LDG RT-RC-100 is rated to tune 4-800 ohm.

When I swap a LDG Z-11ProII for the RC-100 controller, I am able to tune just fine *through* the RT-100 remote ATU, so I know I have good connections. I am able to receive WSPR signals and voice through the RT/RC-100 without or without the RC-100 powered on. The LDG Z-11ProII is rated to tune 6-100 ohm.

The RT-100 is grounded to a copper rod, and located between 150ft of coax from my shack and 70ft of coax from the G5RV.

Is there a safe way to tell if I'm getting DC from the RC-100 to the RT-100?

7261. Re: [LDG-auto-tuners] LDG RT/RC-100 Not Working?

Topic: 7260 Message: 7261

I have that combo. I seem to recall that the manual warns not to short out the coax which carries DC to the RT-100, like running the coax to an antenna switch which grounds unused ports. It sounds as though you may have blown your RC-100.

It isn't as simple as having the cables reversed on the back of the
RC-100 or the RT-100?

John,
(this is my third try, the forum editor kept deleting my typing, so please pardon me if I am a bit terse)
Yes, you need a balun, but not just on the tuner output but on all three cables. I and others have noted that LDG tuners are subject to RFI, so on my KT-100 I put "current baluns" (RF chokes) on all cables: about 12 type-31 ferrite beads with 0.5" id on the RG-214 RF output coax; about 7 turns of the RG-8X RF input coax in a 0.722 id split bead; and about 8 turns of the CAT-5 power&control cable around a type-31 2.400" od torroid core. You can get the ferrite through Amidon Associates for small quantities, while Mouser Electronics has the Fair-Rite equivalents at a qood discount for large quantities.

Amidon 2x31-4181p2 31 Matl Snap-on Beads .514id 1.22od 1.55ht

Amidon FB-31-1020 31 Material Round Cable Beads 1"od 0.5"id 1.12"ht
Mouser 623-2631102002 Fair-Rite 2631102002 31 ROUND CABLE CORE 1"od 0.5"id 1.12"ht

Amidon FB-31-24001 31 Material Round Cable Beads 2.4" x 1.4" x .5"
Mouser 623-2631803802 Fair-Rite 2631803802 31 ROUND CABLE CORE 2.4" x 1.4" x .5"

Amidon 2X31-6451P2 31 Matl Snap-on Beads .722id 1.52od 1.87ht
Mouser 623-0431176451 Fair-Rite 0431176451 31 ROUND CABLE SPLIT CORE 1.52"o x 0.722"i x 1.87"l

If you use CAT-5 cable for power&control, I recommend you pay attention to wire pairing. CAT-5 cable has 4 pairs (8 conductors), and the KT-100 has two control signal plus power. I used one pair for each of the two control signals, and put the other two pairs in parallel for power. Thus, two conductors are used for power, one conductor for each of two control signals, and the remaining four conductors are the pairs for the previous four and are all connected to ground.

You can see photos of my KT-100 installation in the photo area in this forum.

As to the size of the antenna, I recommend that you use a non-harmonically related length. For example, the S9-31v vertical that I have is 31-feet, so it resonates at about 7.5MHz. If it were 32-feet, it would resonate nicely at about 7 MHz, but then would be anti-resonate (end-fed half-wave) at about 14 MHz and would be very difficult to tune. As it is, it is not resonant on any ham band, but not too far out of resonance on any ham band. I would recommend you build your dipole for about one-half wavelength at 17-meters, since the WARC bands are not harmonically related to the other bands.

You might also model your antenna using an antenna simulation such as EZ-NEC since that will show the lobes and nulls that will develop when operating at frequencies much higher than the half-wave frequency.

Here is a link to the photos of my KT-100 installation:

The dc source should be between the coax to the antenna and the swr meter and not between the swr meter and the xcvr. do not use a grounding coax switch or a balun between the dc source and the rt100. Also check the voltage on the dc source as you might have blown thd internal fuse.

Bret,

I had a similar problem with an MFJ tuner (not automatic) several years ago. I did the same thing.....pushed on various components and it started working. But it was short lived. A few days later the problem reoccurred. So, I found a consistent signal, like WWV, and started tapping on components and working switches, until the signal changed in strength. In my case, it was a poor solder joint. The solder joint “looked” OK, but it definitely was not. It was a wire soldered directly to a coil. I cleaned both connection points and re-soldered. Working great ever since. I would suggest that you find the weakest WWV (or CHU) signal, and use that to test for an intermittent connection, switch contact, etc.
Since this is an autotuner, I realize that this is going to be different than trouble shooting a manual tuner.
Good luck.

73,

Steve KC8BW

Thou might try taking the SWR meter out. The RT100 will make a clicking sound when tuning. Also you may not have the appropriate power supply for the RC100. One other thing is to cover the RT100 with a bucket or some other water proof container. Mine is not water proof. I had it repair twice before I covered it with a five gallon bucket. Since then I've had no problems.

Just got mine a few weeks ago. Put it up in the attic (I'm in a CC&R HOA so antennae are forbidden). 85 feet of LMR-240-UF from radio to RT-600 and then another 25 feet of RG-8X to a 4:1 Balun Designs at center feed loop of 235' of insulated poly-S stealth black insulated wire run from under the eave at the peak of second story roof line out through two Live Oak trees to a corner Elm tree and back. Closed loop is in a triangle shape about 25' high. Performance has been great - it will even tune 160m. QSO's with Congo, Jordan, Poland, Israel, etc. on the loop, as well as, excellent NVIS operation on MARS frequencies. QTH is Florida east coast. I run usually 100w but have used the ALS-600 for a boost when needed. Been waiting for this Remote Tuner for a long time and it was worth the wait.

Thank for the reply, Bruce..

My current antenna system is far from fancy, low, short - limited space. A loop would be nice but no trees to hold it up. I wasn't suppose to have an antenna but it has been tolerated and after 8 years it is no longer noticed as a problem.

I wonder if a RT-600 at the antenna feed point, instead in the shack would get more power to the antenna. My hope would be to less power loss than with 65 feet of coax between the tuner and antenna feed point. The next question is how well it will actually work at the rated -40 temperature. It gets cold up here in my part of Canada.

Hello:

I have had my RT-600 for about a month. I have two dipoles each fed with different lengths of 450 ohm line. Each one then is connected to a 1:1 current balun. I'm able to select each one with a remote switch and then directly to the RT-600. No problems tuning each dipole from 80-6 meters. Because each antenna has a different impedance because of the different feedline lengths, the memory function forces me to do a lengthy tuning when I switch antennas on the same frequency. As long as I don't switch antennas I can return to a memorized frequency and the retune is quite fast, 2-3 seconds. Additional code could take care of this but I'm sure my situation is not normal for the majority of users.

I run 200 watts to the tuner and do all my tuning at about 5-10 watts, so far I'm quite happy with its operation. I did send LDG an email asking if there was anyway I could force the tuner to find a better match than 1:3 which I have on a couple of bands. They answered that is was not possible. Maybe some day a software update will address this.

1.3:1 is not a problem for all practical purposes. Anything below 2:1 is adequate.

This is part of the old wife's tales, superstitions and voodoo that is perpetuated mostly by ads for store bought antennas that causes many of us to spent enormous amounts of treasure, time and fretting over the SWRs to reduce it down to the magic 1:1 nirvana. This to me is the biggest swindle in amateur radio!

The greater worry is what the SWR might be on the other side of the tuner if one is using coax out to the antenna. Losses can become significant, even hideous, in a hurry, depending on how high the SWR is, what kind of coax and how long a run.

I put up a G5RV about a year ago, classic dimensions, with ~100' or so of RG8X back to the shack. I noticed that I was getting no replies on 10M and complained on one of the forums. An antenna guru of some renown kindly informed me that the SWR in that system on 10M was likely in the vicinity of 60:1 and virtually all of the power was being dissipated in heat en route to the antenna, leaving a pitiful amount to radiate. My tuner matched this "load" to the transmitter just fine but nobody could hear me!

I replaced this antenna with a 130' dipole fed with 450 ohm ladder line and everyone is happy!

Ken,I understand and still remember the cold as I spent 4 years in Montreal in the sixties. Graduated High School there and a few years of college before joining the USAF. Great time and people were great made several long lasting friendships that exist today there. This of course was before the separatists got hold of things.
Anyway with all the losses I had running the previous configuration it did make a difference both with the new coax and the Remote Tuner.
ORIGINAL:IC-756ProIII -> ALS-600 -> LDG AT1000Pro -> AWM-30 SWR/Wattmeter -> 50 ft RG-8X coax -> Ameritron RCS-4 remote antenna switch -> 25 feet RG-8X coax -> 4:1 balun from Balun Designs at Loop feed point. --- Don't get me wrong this one did work but not exceptionally well. Although the 4:1 balun did make a good improvement when I swapped out he 1:1 current balun for the 4:1 balun.
NEW:IC-756ProIII -> ALS-600 -> AWM-30 SWR/Wattmeter -> RC-600 controller -> 85 ft LMR240-UF coax -> RT-600 -> 25 feet coax -> 4:1 balun from Balun Designs at Loop feed point I intended to shorten the last bit of coax but was too hot in the attic so I left it. I'm sure that would have another significant improvement to performance.
Before using the ORIGINAL configuration i could not tune 160m now with the NEW I can easily. The performance on the other bands has been surprising. I have talked to many DX station over 6,000 miles away using the loop!!!
Anyway the plastic case maybe an issue with the cold outside in those cold Canadian winter so I would put the tuner in some sort of waterproof insulated container, maybe with a small light bulb in it to stay warm during the fridge temperatures. Since I was worried about the HIGH temperatures I wrote LDG and got the response that the RT-600 is rated at 140 degrees F so temps here in Florida attic should be ok. Did not however ask about low temp - LDG folks are quite accommodating you might want to email and task a few questions about cold.

 Is it just my pc or is the font below really small? From:
mailto:LDG-auto-tuners@yahoogroups.comSent: Tuesday, April 14, 2015 2:52 PMTo:
LDG-auto-tuners@yahoogroups.comSubject: Re: [LDG-auto-tuners] Anyone using a LDGRT-600

Ken,I understand and still remember the cold asI spent 4 years in Montreal in the sixties.
Graduated High School thereand a few years of college before joining the USAF. Great time
and peoplewere great made several long lasting friendships that exist today there. This of
course was before the separatists got hold of things. Anyway with all the losses I had
running theprevious configuration it did make a difference both with the new coaxand the

Remote Tuner. ORIGINAL:IC-756ProIII -> ALS-600-> LDG AT1000Pro -> AWM-30 SWR/Wattmeter -> 50 ft RG-8X coax ->Ameritron RCS-4 remote antenna switch -> 25 feet RG-8X coax -> 4:1 balunfrom Balun Designs at Loop feed point. --- Don't get me wrong this one didwork but not exceptionally well. Although the 4:1 balun did make a goodimprovement when I swapped out he 1:1 current balun for the 4:1 balun. NEW:IC-756ProIII -> ALS-600-> AWM-30SWR/Wattmeter -> RC-600 controller -> 85 ft LMR240-UF coax-> RT-600 -> 25 feet coax -> 4:1 balun from Balun Designs atLoop feed point   I intended to shorten the last bit of coax butwas too hot in the attic so I left it. I'm sure that would have anothersignificant improvement to performance.

Before using theORIGINAL configuration i could not tune 160m now with the NEW I caneasily. The performance on the other bands has been surprising. Ihave talked to many DX station over 6,000 miles away using theloop!!!

Anyway the plasticcase maybe an issue with the cold outside in those cold Canadian winter so Iwould put the tuner in some sort of waterproof insulated container, maybe with asmall light bulb in it to stay warm during the fridge temperatures. SinceI was worried about the HIGH temperatures I wrote LDG and got the response thatthe RT-600 is rated at 140 degrees F so temps here in Florida attic should beok. Did not however ask about low temp - LDG folks are quite accommodatingyou might want to email and task a few questions about cold.

Bon Chance Mon Ami! WellI had to learn a little French being in Quebec for four years.73 Bruce/NN4BJ

Hi Jim:

Yes I realize the difference between 1:1 and 1:3 is not a problem to the transmitter and certainly does not change what the receiving station is hearing, it was only a question to LDG about the ability to change the tuning SWR range.

Thank you for your input.

Do you mean 1:1 and "1:3" or "1.3:1:?" 1:3 is getting up there. I read it as 1.3:1 on your first inquiry.

My itty bitty AT-Sprint, original model, circa 2003, puts out a solid 3 watts into a 3 to 1 SWR. I've made many contacts with a 31' Jackite pole supporting a 33' long wire and no impedance matching device. Usually the best I can get without the Z-100 is SWR=3, by fiddling around with counterpoise length.

My LDG Z-100 seems set to "typically" seek a SWR=< 2.0. Sometimes it gets to <1.4, but often it stops tuning around SWR=1.9 to 2. Haven't bothered to figure out, since neither my itty bitty AT-Sprint nor my Drake TR-5 minds SWR=2 or even SWR=3. The Drake seems to cut back on power if SWR>3, but I've run it when something's wrong with the feeders, and SWR can only be tuned to <5 or so, and made contacts.

Folks are hyper these daze if SWR >1.001 or so. Back in the early daze, we'd just "tune out" the reactance the final tank circuit of the rig - and pray that we didn't generate harmonics enough to get a pink ticket if we wuz heard outside the band on a harmonic level.

Dunno about the RT-600, but I have the RT-100. I find it odd that on a manual tune, it sometimes rattles through matches with "1.x" in the process, but settles on something higher. Multiple manual tunes, showing lower SWRs encountered, but always lands higher with "2.x" or above.

That doesn't sound right...

Mine does too. It sequences through a bunch rapidly, often including a 1:1, or 1.2:1 then settles on a higher one, 1.7:1. I doubt it makes much difference in signal, but is disquieting to observe.

Yes I have the same operation here. It shows a better match as it is looking for one, than what it finally settles on. That was kind of the basis of my question to LDG, is it adjustable ? And they responded that it was not adjustable. I would hope they address this in software revisions,

Most likely you switched it to Semi mode. Not sure what the sequence is
on the 1000 but on my 200 it is Func and C Dn/auto to switch it between
semi and auto modes.

I have an AT-600PROIII, and it may be the same. You will have to read the manual, but, on mine, when a certain key sequence is pushed (quickly, I think), it will toggle the auto tune on or off. On mine, it is the "Func" and "C Dn".
The tuner cannot handle more than a hundred or so watts when tuning, so they suggest hitting Func C Dn after tuning and before applying full power.

You may have hit the sequence by mistake, or the tuner may have done it itself. Check your manual for the sequence, and see if that makes a difference.

7291. LDG answers to RT-600 questions

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-04-23 03:51:02 UTC
From: ge6146@...
Topic: 7291 Message: 7291

I recently send the following RT-600 operational questions to LDG, here are my questions and their responses.

Question 1
The manual page 5 states: "The RT-600's latching relays hold the tuned configuration indefinitely, even when DC power is removed".

The manual page 14 states under Bypass: "When the RT-600 is turned off (Power button in the off position, Status LED off), the tuner is bypassed: RF from the amplifier is passed directly to the antenna with no matching."

I asked; "Which way is the RT-600 designed to operate?"

LDG answered:
"When the DC power is removed, the tuner goes to bypass. It does not have latching relays."

Question 2
The lack of numerical SWR values for the following manual statements. "Final SWR match higher than usual", "acceptable SWR match", "if the SWR is too high". What are the actual SWR readings or SWR ranges associated with these statements which are scattered in the manual?

LDG answered:
"The system that we have does not have a way to provide SWR readings to the user, they would need to look at the radio".

Question 3
As an example, on 7.055 Mhz one of my dipoles tunes with an final SWR of 1.3:1. When I switch antennas and transmit on the same frequency, the SWR is over 3:1, the RT-600 does not retune. When I conduct a manual tune, it also tunes to 1.3:1. At what SWR does the tuner say, the SWR is too high and begin an automatic tuning as stated on page 13?".

LDG answered:
"For your issue, the tuner never retunes on the same frequency. That keeps it from going into a perpetual tuning cycle every time you key the radio."

I still have some issues with the answers to 2 and 3 but I will not go into them in this posting, I just wanted to pass along LDG's responses to my questions.

Interesting!

I have the RT/RC-100 remote atu, and it does indeed latch when power if off.

On a G5RV 102ft dipole, the SWR profile across 80m-10m varies markedly depending on which band I tune to before powering off the RC-100.

Not always

My mate on my recommendation bought the same AATU that I bought , the Z100 , Plus mine came with leads for the Icom 706 and Yaesu FT 857 his came without

He rang up the suppliers who said they no longer came with leads they had to be ordered and paid for separately

He returned the unit and asked for a FULL refund he got a refund less carriage , he got his full refund EVENTUALY but it cost the supplier dearly

Same supplier puts guarantee tags on equipment saying if tag is broken the guarantee is void

I can install batteries with out breaking a guarantee tag , but then I'm a magician (not)

Regards

David (G8UVE)

The manual mentions nothing of the FT-920, so I would say "no". You will probably need to go for a general LDG ATU like the AT-100Pro II or suchlike. The YT-450 works with the FT-450, FT-950 (and if the case with the newer YT-1200), should work with the FTDX-1200 & FTDX-3000. Even though the CAT port is 9 pin serial, you will probably find the CAT commands are different.

Cheers,

Mike

Alex, I am not sure what you are talking about. The FT-920 and FT-450 couldn't be any more different if they tried. The LDG YT-450 ATU is a control cable tuner only, there's no RF sense function to be fully automatic. You have to press the button on the ATU and it sends CAT control signals to the rig to adjust power and mode, do its match and return the radio to the previous power and mode.

No it's not. The YT-450 is not a good tuner choice for the 920. It's designed to talk to the 450 and 950 (which have common firmware).

7306. Z100 Rev 2. 0 pic not triggering tune up

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-05 11:12:27 UTC
From: Chris Reed
Topic: 7306 Message: 7306

Hi Group,
I recently picked up the above at a rally. It was understood to be non functioning so it's fare to say it does what I was told it would. That said, I'm always up for learning something new, so I figured if It can be made to work, it'll come in handy when portable on holiday or for use in the van.
On power up I can get a green led to flash on once and I can get the red led on briefly with a extended push. After which I get nowt while keying 10w. Antenna is a hf trap dipole cut for cw. There is no attempt to tune what so ever. And repeated presses do nothing.
Power cycle gets the lights doing the same.
I've yet to put a meter anywhere near but assume I've probably got a processor fault as there's not much more in the box.
Ideas on a post if poss.
Thanks for the use of the group.
Chris

7307. Re: [LDG-auto-tuners] Z100 Rev 2. 0 pic not triggering tune up

Yahoo group: LDG-auto-tuners (2010 — 2017)

From: Hank Greeb
Topic: 7306 Message: 7307

Chris:

I suggest you look at the SWR the transmitter is seeing. The unit will go into bypass mode if it sees a satisfactory SWR upon power up or first tune.

My Z-100 works as follows:

I power it with 9 to 12 volts from a pack of AA cells. If the cells are weak, it will not perform. So, when I run into a situation where the unit is not running, I check the cell pack and recharge (if I'm using my 9.6 volt NiMH pack) or replace the cells (if I'm using a pack of alkaline cells)

I then connect transceiver, SWR/Wattmeter, LDG Z100 all in series, then to the antenna. I key up the rig, and run 3 to 5 watts into it (I think one can use more, but it works fine with 3 to 5 watts) I always have a SWR meter in line.

While transmitting, I press and hold the tune button, it runs through a series of clicks to find the optimum SWR, typically less than 2.0, often much lower. The green light comes on, and usually stays on for a few seconds, sometimes longer.

If I just click the tune button, it searches only the values stored in memory.

Since you say that your unit does not search for a low SWR there probably is something wrong internally.

But, before you dig into the internals, perhaps you have RF Feedback into the unit from antenna currents on the outside of the coax feed to the antenna? That's one very common problem with the computer controlled tuners. RF chokes (UNUNs they are commonly called, can cure this problemme. I'm no expert in this matter. You might try your unit at a friend's place where a similar tuner works satisfactorily to be sure it's not something external to the tuner at your place.

As you say, it could be the control unit (CPU) or it could be one or more of the inductors? There's a sensing unit for detecting SWR. There's considerably more that "just the control unit."

You might ask LDG to price a "look-see" diagnosis of the situation.

Good luck with your "pig in a poke" I got mine for $40 USD, because the case was warped from heat! It looks terrible but the innards work fine!

7308. AT-100Pro issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-05 16:36:37 UTC
From: w4grj@...
Topic: 7308 Message: 7308

I have the AT-100Pro feeding 100’ coax to G5RV. Using the TS-440sat, the 440 built in antenna tuner works fine on 14.300
However, the AT-100 cannot get a match…yes, I have the 440 in bypass mode.

The AT-100 seems to work fine on all the ham bands except 20 meters.

We have this setup as remote rig at our club so we are trying to get the AT-100 in so we can use on all the ham bands.
Any Ideas or suggestions appreciated.
Jack

Thank you Hank.
I'll clear some space on the bench and set it up with a meter either side and be a bit more methodical.
The rig I'm using is a k2 and when I did another short test it looked like the k2 shut down. I'll give it another govat the weekend when I get back from work.
I'll update when I have a bit more to go on.

7310. AT-897 (nog plus) defect!!??

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-08 21:53:12 UTC
From: pd3oes@...
Topic: 7310 Message: 7310

Hello,

A half year ago (I used it for 2 years and both it second hands) mine AT-897,witch I only used with min FT-897, did not tune anymore.

Yesterday it looked in to the problem. Seems that the tuner tunes and can not find a low SWR. But when he finds a workable SWR and I give a carrier in CW it looks that the SWR stays low for a fraction of a second and than moves up to HSWR. Even on a dummy load. And on all the bands.

I read it could be a reflected power issue. But with a dummy load or a FB23 ant. on 10, 20 mtr. Witch I now work without a tuner, I don't think this is the problem.

I measured that relaid K8 not change in set or reset. Is this a relay problem?

Please some help?

73's PD3OES can read in German and English but prefer Dutch ;-)

Andre

7311. RT-11 Dead

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-09 01:00:42 UTC
From: jilly@...
Topic: 7311 Message: 7311

Hi
I've been away from the hobby since I became disabled but I've decided to put my shack back together again & I've found my RT-11 doesn't do anything when I press tune on the control head. No sound at all comes from the tuner. (I think I recall it making relay noise as it worked before.... that was almost 10 years ago. It's just been sitting inside since then.)
I have the tuner attached to the control head via a DB-9 cable to the control head, & I didn't do any sort of radio control. (The remote uses a wall wart.)
The green light comes on the remote saying the SWR is OK but the radio's SWR said 3:1 (which is correct for that band on that antenna).
I'm going to replace the DB-9 cable but other than that I'm not sure if it is worth it to proceed further? It has the original chips/firmware. If the cable is OK then I guess I can open it up but my soldering days are past. Any other ideas?
Thanks
Jilly

7312. Weatherproofing

I have an RT100 bolted near the bottom of my homebrew S9v31 clone. It has done a decent job so far but I worry that it is not weatherproof.

Since it seems to have been designed to spend its life on a tower leg exposed to the elements, so why it isn't weatherproof end is a puzzle.

What are some clever ideas for shielding it from the wet and heat etc?

Well, not so clever, but:

1. Silicone grease on bottom panel gasket
2. Gallon ziplock bag over the top, stapled and taped at bottom
3. Small plastic trash can inverted over the whole unit, with gaps/holes cut for input/output

Keeps critters/rain/snow out so far!

I'd add that some periodic rechargeable (by low temperature home oven bake) silica gel in the bag or enclosure might also help.

If the tuner makes a "blip" sound, and flashes lights, then it does not
like the antenna. Watch the tuner when you try it again.

Topic: 7321 Message: 7325

The G5RV on the lowest frequency band it is "supposed" to be used, has a SWR=>9, highly reactive, so it's hard to tune out the reactance. Folks say it can be tamed with 70' or more of RG8, but that means that lots of power is consumed in the coax. Many tuners won't handle the reactive load seen at the end of the ladder line. Typically, it works better to run the ladder line into the shack and either use a balun prior to the ATU, or, better yet, an inherently balanced, wide range tuner.

Actually, if one looks at the original article by G5RV, he describes a 20 meter antenna, 102' long, center fed with parallel feeders and to convert the impedance to near 50 ohms resistive. He doesn't claim that it's a multi-band antenna.

Others noted that resonance is near on other bands, but usually forget to note the SWR=>9 on 80 meters.

AND, when you add 70' of coax to the connection between the twin lead and the computer, you'll lose more than 50% of the power delivered to the antenna is coax loss, especially on 80 meters where the SWR @ the twin lead is 9/1.

But, you WILL get out, there are many folks who use the G5RV with such a "matching device, power sucker" between the antenna and the tuner. So, as my pappy was wont to say, while we were tending a potato field at my Uncle's Farm, "To each his own, potato row."

Thanks Alex

I've had a look at MFJ ATU's (MFJ 939)

The actual connection at the back of the ATU is different

I already have the Z100+ using it on a 706MK2G but would like to use it on FT817 ND

The Z100+ has had little use and I don't really want to sell it

I know this group is watched by a LDG staffer and I thought they may have popped up and pointed me in the right direction

Of course Dayton has just finished ;-))

Thanks again

I should add, that the RC/RT-100 is pretty robust. I hooked up the RC-100 backwards and RT-100 backwards as well, and tuned up at 25W CW. Finding something amiss, I fixed the RC-100 hook-up and tuned up again, then finally checked the remote and corrected the hook-ups. All worked fine thereafter. They have engineered some safety into the units!

Thanks Alex

I've had a look at MFJ ATU's (MFJ 939)

The actual connection at the back of the ATU is different

I already have the Z100+ using it on a 706MK2G but would like to use it on FT817 ND

The Z100+ has had little use and I don't really want to sell it

I know this group is watched by a LDG staffer and I thought they may have popped up and pointed me in the right direction

Of course Dayton has just finished ;-))

Thanks again

David (G8UVE)

7334. KX3 and Hardrock50 with LDG Z 100

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-26 18:32:21 UTC
From: arrillaga@...
Topic: 7334 Message: 7334

Hi All, I am considering getting a Hardrock50 to use with my KX3 and would like to use my existing
LDG Z 100 when needed to make every thing happy. Have any of you tried such a combination? How did it work? Any pitfalls? Thanks for any insight. 73 Gene KF6ZYD

7335. Re: [LDG-auto-tuners] LDG Z100 + ATU

Topic: 7327 Message: 7335

Thanks All

For pointing me to the Cheapham site

Unfortunately that site doesn't resolve my problems

I'm looking for a cable that will interface the LDG Z100+ to a Yaesu FT817 ND

The cable that is shown is for the Z100+ to the Yaesu FT 857

Looks like I'll have to think of another avenue

Thanks for all the help

The Plugs are different at both ends

That's the problem

Look at the back of each ATU and then look at the back of each rig

regards

Now that I think back when I had the FT-817, I believe David is right and that cable I posted a link to will not work on the FT-817. The 817 uses the CAT port (to the Z-817 tuner) where the 857 uses the 3.5mm ACC jack.

Subject: Re: [LDG-auto-tuners] LDG Z100 + ATU

Now that I think back when I had the FT-817, I believe David is right and that cable I posted a link to will not work on the FT-817. The 817 uses the CAT port (to the Z-817 tuner) where the 857 uses the 3.5mm ACC jack.

Thanks All

For pointing me to the Cheapham site

Unfortunately that site doesn't resolve my problems

I'm looking for a cable that will interface the LDG Z100+ to a Yaesu FT817 ND

The cable that is shown is for the Z100+ to the Yaesu FT 857

Looks like I'll have to think of another avenue

Thanks for all the help

Thanks Alex

I've had a look at MFJ ATU's (MFJ 939)

The actual connection at the back of the ATU is different

I already have the Z100+ using it on a 706MK2G but would like to use it on
FT817 ND

The Z100+ has had little use and I don't really want to sell it

I know this group is watched by a LDG staffer and I thought they may have
popped up and pointed me in the right direction

Of course Dayton has just finished ;-))

Thanks again

David (G8UVE)

7342. LDG AT-600 Pro II Keeps reuning on 80 metres

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-27 21:48:23 UTC
From: rolandbrade@...
Topic: 7342 Message: 7342

I have a fairly new AT-600 Pro II Autotuner.
I tunes perfectly well on all bands with my Trap inverted L.
However on 80 metres it keeps going off tune and retuning during a transmission.
Anyone else had this and can someone give my any suggestions.
I looked inside the box to see if anything was getting hot but all looked as clean as the day it was made.
I was wondering if it could be a dirty relay.
The max power I run is 100 watts on all bands but normally only run 15 - 25 watts on JT65 as I use this mode mostly.
If I bypass the ATU and use the rig's internal tuner all seems fine.
Any help or suggestions would be appreciated.

Roley G3VIR

7343. RE: [LDG-auto-tuners] LDG Z100 + ATU

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-27 22:16:17 UTC
From: Michael D Earls
Topic: 7327 Message: 7343

Other than buying the LDG Z-817 or one of the other tuners designed for the 817, I came across this page where K5LAD talks about his homebrew antenna for his 817.

http://www.hayseed.net/~jpk5lad/817%20Tips%20and%20Antennas/817%20Portable%20Antenna.html

He has his 817 attached to a Z-11 and mentions that he previously had used an MFJ-901B.

The page includes numerous photos, but I didn't spot the tuner cable.

This assumes no physical differences between the 817 and 817ND.

His email is at the bottom. If still valid, he might offer some insight.

7344. LDG Z-100+ Remotely Mounted Switch

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-27 23:34:16 UTC
From: robert6594j@...
Topic: 7344 Message: 7344

Greetings,

I recently purchased the LDG Z-100+ tuner with the intention of incorporating it into a custom portable enclosure along with an FT-857, power supply, and Pwrgate. Because of the design of the kit, I'd like to remotely mount the "tune" button and the two LED's on the front panel. I'm sure relocating the two LED's is easy enough, but I'm not able to find any information regarding the switch- no part number or no schematics on the pins. Would replacing it with any momentary switch work, and which connections are which? This is the first time I've attempted a mod like this, and the LDG tech was of no help, just sent me a link which provided no info.

Thanks for any info you have!

-Robert

Hi Mike

Thanks for the input

As I said in an earlier email I already have the 857 and z100+

I am hoping to interface it with the 817 I have having the same facilities as the 857

There's a lot of information around

I don't want to do any damage to the unit

I'm not sure but I think the only way to get it repaired is to ship it back to LDG in the States

I don't think there's any one who has the information to repair it this side of the "pond"

I believe LDG are reluctant to let the information out to the general public in case it gets hijacked and I don't blame them.

You may be getting RF into the Tuner. Is the tuner at the inverted "L"
or is there some coax between the end of the inverted "L" and the
tuner? If there's coax, try a common mode choke (either several turns
of coax wound over a 2" or so diameter PVC Pipe, or a few big ferrite
clamp on units at the antenna end of the coax and similar common mode
choke at the tuner.

Common mode RF can really bolix the SWR sensing circuitry of an ATU.

My suggestion was that K5LAD apparently has successfully used two different tuners with the 817, which were not designed for it.

Therefore, he might provide info on how he did it.

The Z-100 is NOT an Auto tuner - i.e. it does NOT sense the SWR unless you manually push a button. You May connect a two wire connection to the "tune" port in the back of the Z-100 and run it to the rig, but you still need some way of telling the Z-100 to tune. This is usually done by a switch at the operating point. If there's a "tune" switch on the FT857 perhaps it lowers the power to a lower level (<10 watts or so) and then "grounds" something on the back panel to the ground chassis ground. This could be used to connect the 857 to the LDG Z-100. There ARE a host of LDG tuners which are auto tuners, just not the Z-100.

When you say you're running 100 watts, is that 100 watts SSB, Digital, AM?

Although the tuner is rated to 100W (I think actually 125) that's on SSB
which has about 30% average power ratio when compared to peak power.
Typically Ive found once the tuner finds a match it'll only retune if it
gets hot due to too much power.

When you say you're running 100 watts, is that 100 watts SSB, Digital, AM?

Although the tuner is rated to 100W (I think actually 125) that's on SSB which has about 30% average power ratio when compared to peak power. Typically Ive found once the tuner finds a match it'll only retune if it gets hot due to too much power.

Is it possible to interface the Z-100Plus to the FT847? I need a new tuner for it and LDG doesn’t make the YT-847 tuner anymore. I figured out how it interfaced to my FT857D and figured it would not be that hard to make it work on the FT847. Anybody have any other ideas?

Mike
Many thanks for your answer.
That's solved the problem, however I am still searching for the reason why it does this on 80 metres.
For Josh, this tuner is rated at 600 Watts. Spec says : 600 Watts SSB and CW, 250 watts on 6M. 250 watts PSK and digital.
I don't have the capability of running more than 100Watts.

Thanks to everyone that replied.

7353. LDG Z-11Pro II Tune Memory

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-05-30 11:37:11 UTC
From: cbjesseeNH@...
Topic: 7353 Message: 7353

I am using my LDG Z-11Pro II to tune a OCF dipole while running WSPR propagation on Win7(64). I run through all the bands tuning on 25W and see all tune to < 2.00. Then I set power to 5W on my FT-897D/SignaLinks USB set-up and band-hop. In many cases the short 2-3sec tune-up before each Rx isn't long enough for the tuner to land on the memory for the last tune at frequency and it stops at > 3, as seen by LEDs, and > 100 on SWR meter.

Any solutions apparent?

Topic: 7342 Message: 7354

The reason it may do that on 80 is because the SWR is too high on 80. If the SWR is over 2:1 it will "hunt" for a match forever. I do not know if you are familiar with tuners in general and the LDG line in particular, and if you are, just disregard this missive. However: Warning: I am going into educational mode! Educational content, you may want to hit "delete"!*
Matchers are by nature black magic. Some say you are "foolin' yer transmitter" (no, not really), but what you are doing is taking a reactive load that may or may not be resonant on the frequency in question and transforming it (a matcher is indeed a transformer) to a 50Ω load. If you are using an end fed wire (longwire) directly into the tuner (matcher), you will use the coils and capacitors in the matcher to resonate the antenna *_and_* transform the load to 50Ω! However:
On a coax fed antenna, if you are using the antenna off of the resonant frequency, the matcher has to deal with a high SWR coming off the feedline, a really flaky reactive load, and a load that is far from 50Ω. Lot of work, and sometimes it can't do it. Add to that the losses on the feedline for an off resonance antenna (high SWR on coax causes bad losses, sometimes extreme, especially in long runs). Lesson here, don't use coax fed antennas on all bands unless the coax run is short! (Use balanced line instead.)
Often, the antenna is simply out of the range of the capacitors and coils in the matcher/tuner, and the SWR stays high. On a manual tuner, it simply means that you end up either with a high (up to 3:1) SWR, or a really bad SWR that is off the scale. This is simply out of any realistic operating range of modern radios, who like less than 1.2:1, at 1.5:1 will cut power to about 50 to 75%, at 2:1 less than 50, and at 3:1, they refuse to budge, just take their bats and go home. Older tube types with hefty tank circuits simply didn't care, having all the coils and caps they needed.

LDG tuners/matchers are whiz-bang, but due to their construction, are only good for a certain range of impedance. Beyond that, they cannot go. Some of the older manual tuners (I have a Heathkit SA-2040 that will tune the gutters on your house!) can easily match a 40 meter to 160, but the LDG is not going to do that.

Now, I suspect that your inverted L may be a Marconi type, fed with coax and grounded somehow. If it is, you are going to have trouble. I would respectfully suggest getting some ladder line, feed your inverted L as a center fed wire flattop, and run it through a balun (LDG makes them; I suggest a 4:1). With a 102 to 135 foot antenna like this, you can expect to tune from 80 through 6 with little trouble. (This is my setup BTW).

When tuning on 80, see where the lower bank of lights stop. If they are stopping at 1.7 or less, then you probably have an RF problem in the shack. If it is at 1.7 or higher, your antenna is out of range of the matcher.

Alex
Very many thanks for putting pen to paper or should I say fingers to keyboard!!
Yes you are so right. I fully understand all you have said having been in commercial and military radio research engineering for over 50 years.
This inverted L is of the trap type and is resonating at about 3760. The SWR is pretty good without an ATU as I trimmed it. I did cheat a bit in

that I took the W3DZZ design measurements. Then made a trap for 80 so that

it covered 160 as well. 3760 is a bit high for me but I will sort that later. Yes, I do use a balun which I constructed myself. After all they are not hard to make as long as you use the right type of core.
I think we are getting to the swap stage, just to confirm that it is as suspected and not the ATU itself.
Alex once again thanks for taking the trouble to send the message, I am sure it will be of help to many people on this group.
I liked the photos on your QRZ page

Hi Roley,

I almost gave up on my 1000pro2 for the same reason.

I had hoped it would be a plug and play solution to running my 88 foot center fed Zepp on all bands with an amp, and instead primarily promoted the consumption of alcoholic beverages.

A friend suggested measuring the antenna with an analyzer across each and then testing at various power levels.

Long story short it became apparent in the end that I had separate common mode, balun saturation and complex load issues that I eventually exorcised with a new balun (had to go to 4 stacked T200s) lots of ferrite, relocating a feed line, and changing the feed line length.

After having done that I still think the 1000 wants to retune more often than the 200pro did, but at least there were several reasons for its initial behavior, and it's much quieter now.

Good luck.

Scott ka9p

Make something good happen!

Topic: 7357 Message: 7357

I was attempting to work the Falklands last night on JT65 with my FT897D. I have a 135' OCF fairly high and did a primary tune up. So far so good. But as the transmission progressed the SWR increased to above 3:1. During the next cycle this behavior repeated. Normally I would suspect a bad joint but the balun and wire connections were just inspected. AND it does not happen on other bands in similar conditions.

I'd remove the cover and, with the transmitter is unkeyed, but after a transmission, see if there is any coil or capacitor heating. Something would have to get pretty hot to do what you describe, so it they are room temperature or slightly warm, it's probably not the tuner.

Running too much power ? I believe its only rated for like 20-30 watts on digital

7360. AT-200Pro not retaining memories on 15 and 20m

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-06-09 23:43:39 UTC
From: fudgies@...
Topic: 7360 Message: 7360

Sorry if this subject has been covered before here!

For the past week or so I have noticed that my AT-200Pro goes through a full tune cycle especially on 15m but also sometimes on 20m but it's OK on all other bands. I'm using a 66 foot OCFD and tuning is done at 10 watts on CW. If I tune on 15m then QSY to another band it runs a full tune cycle when I return to 15m, it happens to a lesser extent on 20m . It's only been happening for the past week it was working fine up to then.

When it retunes it holds the tune settings so unlike some similar problems that I've read on here it doesn't start to retune during a transmission, only when I leave 15m (or sometimes 20m) then return again.

Any ideas or help with this would be appreciated!

If you check your tracking number with your shipper and verified that it was delivered then all you can do is wait. This topic comes up on a somewhat regular basis. Some repairs are back in a couple of weeks and some much longer and they don't respond to calls for updates.

7368. RE: [LDG-auto-tuners] Contacting LDG

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-06-10 23:11:48 UTC
From: Michael D Earls
Topic: 7361 Message: 7368

This is their response to an earlier inquiry:

Virgil and all. We used to say repairs take up to 4 to 6 calendar weeks for repair, but that was just too generic and looked like a long time. We rarely ever reached that maximum time frame anyway, but we said that as a catch all. Now we just say it will be done as soon as possible. It's an odd occurrence at LDG that we get more than 7 or 8 units in for repair, so most of them are done in just a week or two.

The number of units sent back is so low that we only have a part time person that goes over the really troubled units a couple of days per week. We have a first level technician that looks at them to see if the problem can be replicated or not and can send the unit back (75% of the time there is no issue) or pass it along to a technician. The tech receives units a couple of batches per week and goes over each unit to make an initial determination if it can be repaired or if it's beyond repair.

Finally, if it can be repaired, the technician will do the repairs in the order that they receive the units. There is no way to tell at this point how long it will take to repair any individual unit. It completely relies on the number of units ahead and the complexity of any units already in the queue.
So you see, there is really no way to individually track down any particular unit while it’s in process. This is why we say we’ll contact you when it’s complete. It could be complete at any one of the several steps. It’s by far, the most efficient system possible give the resources.
Taking the time to set up a tracking system so a few units could be tracked through each step would be extremely inefficient. Obviously we could do it, but it would certainly add a significant amount of time to each unit sent in for repair, whether they we returned with the first few days or it ended up with tech for a detailed checkout.
Everyone gets an e-mail as soon as we are finished. We make that very clear. Asking for some kind of status along the way only delays the entire system.
We’ve been doing this a few years and know that there are more customer oriented systems out there, but none are more efficient and certainly not faster than what we currently have implemented.
I hope this helps in understanding the system.

I am having the same problem with my ICOM 7600 and the AT 600 Pro II with a butternut vertical antenna. The tuner works fine with my hexbeam, but for whatever reason I get the lost tuner RF. I checked the vertical with antenna analyzer and the swr is in the tunable range (i.e. way less than 3:1 swr). Also, when I use the internal tuner on the IC7600 it tunes the vertical fine.

Wondering if you or anyone else has found a solution.

Topic: 7370 Message: 7370

I am having a problem with my AT 600 Pro II tuner and ICOM 7600 with a Hustler vertical antenna. I have all the interface cables connected. The problem is that when I tune, I get the lost tuner RF error message on the tuner.

The tuner works fine with my hexbeam, and it did work fine with the vertical a few months ago. But now for whatever reason I get the lost tuner RF message with the vertical. I checked the vertical with antenna analyzer and the swr is in the tunable range (i.e. way less than 3:1 swr). Also, when I use the internal tuner on the IC7600 it tunes the vertical fine. I’ve tried both the automatic and manual tune cycles and I still get the lost RF message.

Wondering if anyone else has had this problem and found a solution. Is there a way to “reset” the AT 600 Pro II?

Todd,

Sounds like an RF in the shack or a poor ground issue. Add RF chokes to the DC power cable to the radio and tuner. If you use an interface cable add an RF choke on that.

Todd I went through all these problems with my AT-600 pro and did everything you did plus more.
In the end I started going round every piece of equipment. I noticed that my rotator did not have a chassis earth. I added one and connected to the station earth.
Oh, what a surprise all my problems were solved! maybe this is the next step for you.
Good Luck

7377. Re: Using auto tuner at multi-transmitter (Field Day)

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-07-01 14:09:08 UTC
From: w_r_adams1@...
Topic: 6201 Message: 7377

I'm back to report success at the 2015 ARRL FD using a remote AT-100PRO in a multi-transmitter environment. The Mansfield Johnson Amateur Radio Service club operated low power (100 watt transmitters) in the 3F category The site included 4 HF stations including the one dedicated to the GOTA position as well as yet another transmitter at the VHF/UHF position. These transmitters fed a variety of antennas including 2 3 element tri-band Yagis, 1 2 element tri-band quad, 1 40 meter 2 element quad, a 2m, 6m, 70 cm Yagi stack, an 80 meter half wave dipole and our 136 ft. open wire fed doublet at 30 feet above ground level. Additionally we are located approximately 5 miles from a 50 kilowatt AM station and 6 miles from most of the DFW area television station transmitters and all the RF infrastructure associated with modern suburban life. At our site our antenna analyzers are overwhelmed by background RF.

The FD operations were out of the fire training room that serves as an alternate EOC for the city of Mansfield, TX. One of the HF positions was dedicated to the cw mode and this station was paired with a tri-band Yagi and the open wire fed doublet, tuned with my AT-100Pro. A pair of bias Tees were constructed based on Phil Salas, AD5X, article "Build a 3-amp Legal-Limit Bias-T that Covers 1.8-230MHz" to supply power to the remote ATU via 175 feet of coax. An LDG 4:1 balun was used at the antenna 1 output of the AT100Pro to connect to a run of approximately 55 feet of 450 ohm window line. At the operating position, a bias Tee was fed by the position's 12 volt power supply and the transceiver (an Elecraft K3). In turn the station bias Tee supplied power and rf to the coaxial cable running out to the remote tuner. The remote AT100Pro, 4:1 balun and a bias Tee were housed in a plastic Stanley tool box mounted on the ground and the feed line dressed approximately 3 feet over the ground until it turned up to the center of the doublet. The ATU was left in automatic mode for the entire operation.

During the FD exercise, the cw operators preferred the Yagi on 20 and 15 meters while having more success with the doublet on 80, 40 and 10 meters. Only 2 trips to the tuner were necessary during the event. In both cases, when the AT100 failed to match, it was discovered that the output had switched from antenna 1 to antenna 2. Perhaps better grounding of the ATU will correct this issue in future deployments.

After all these years of not trying the autotuner in this situation, I'm now a firm believer in including it in the toolkit. I let theoretical issues stall real fun for too long!

Add a length of coax to the antenna. This will not really fix anything,
but may just allow the tuner to tune on 40 meters.

From: K
Topic: 7380 Message: 7380

I am looking for an automatic tuner to go inside a TenTec Orion transceiver. I think the LDG number is OP-11, although TenTec also had one with their own number on it. I have been told it is the same tuner as in the TenTec Jupiter as well, but am not 100% positive of that.

Does anyone have one, or know where one might be found? Or any info of any sort?

Thanks.

I am trying to find a cable to fit my FTL meter. It has not worked properly since I bought it last year and I have had to move the cable ends around in the connectors to get it to work. It is the end with the 90 degree turn, and unless I hold it with pressure to the side it just won't work no matter if I connect to to the radio or the meter. Very frustrating. I sent an email to LDG and the reply was "OK", so I don't know if they make it available or how to order it if they do. Taiwan is not known for making quality products anyway.

Actually a 9:1 would be best if you are feeding with 50 ohm coax.
Then a ugly balun at the tuner output to reduce common mode current.
A 1:1 on the output of your tuner to the long wire if directly feeding the wire.
You may need a 1:1 on the input if you have common mode troubles.
Without any further info on the antenna, installation, type and model of tuner,
etc., it is impossible to give really factual info.

I for got to add that if using an LDG tuner which can match up to 1000 ohms , I believe, Then a 4 to 1 will bring down the 2 to 5 K resistance to under 1K. The tuner will need a good ground at the antenna base(feedpoint). Or possibly avoid any half wave lengths of wire to avoid the high impedance.

None. Put a banana plug on the end of the wire and plug it into the SO-239 for the antenna. The tuner should wring the swr out of it just fine.

There is an argument for using an impedance transformer with a long wire. So it's not acting as a balun and that can make things confusing since people who use a transformer like this tend to call it (incorrectly) a balun.

Take a look at this website and you'll see what I mean.

http://www.m0ukd.com/homebrew/baluns-and-ununs/91-magnetic-longwire-balun-unun/

So, on this website, the designer calls it a balun. But if you read the comments you'll see what it really is. Semantics aside, using an impedance transformer can be a good move.

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-07-09 13:48:46 UTC
From: Bill Adams
Topic: 7382 Message: 7387

The confusion in this discussion comes from the coincidence of a 9:1 impedance transformation in a balun device (50 ohms : 450 ohms) and a 9:1 turns ratio RF transformer that provides an 81:1 transformation (50 ohms : 4,050 ohms). A half wave wire presents an impedance of 3 to 5 kilohms providing reasonably good matching for the 9:1 turns ratio RF transformer.

Since the LDG Autotuners provide a 10:1 impedance match, a 50 ohm source can be matched to a maximum of 500 ohms or a minimum of 5 ohms. In his FDIM 10 paper examining the inverted L antenna, Cebik suggests a length of 85 to 90 feet as this length presents less than 1000 ohm impedance on most HF bands. Perhaps following that logic, a length can be determined that presents < 500 ohms for direct connection to an ATU.

7389. Re: [LDG-auto-tuners] new antenna

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-07-09 14:12:37 UTC
From: Hank Greeb
Topic: 7382 Message: 7389

I sincerely believe that my LDG Z-100 will match considerably greater than 10/1 impedance match. ARRL testing goes up to SWR 16 with a match on 80 through 10 meters.

I've rarely run across an impedance the tuner won't match. This includes weird impedance which cause a 4/1 LDG Balun to overheat @ 100 watts, probably because of too high current. But the LDG Z-100 still makes a match with SWR <2.0.

Note, I don't have an impedance meter, so I use the Edisonian method of adjusting the length of feed line - I find a length which works by trial and error, and then stick with it. This method has worked for some 64 years of hamming, which may be a testament to my incorrigibility or my stupidity, or a tribute to serendipity.

Note 2: From other reviews by ARRL, it appears that the "range" for later versions auto tuners is less than with the Z-100. So, the mention of 10:1 impedance match may be accurate for the models in current production.

Topic: 7382 Message: 7390

Thanks Hank,

Yes I picked up the 10:1 SWR range from an ad, but checking the specs on my old AT100Pro, the HF range is 6 ohms to 1000 ohms, with a 4:1 balun extending the upper range to 4000 ohms. So it would seem that an 85' - 90' wire configured as an inverted L and plugged into my tuner would provide full HF coverage less 60 meters. Gotta try it.

I hope this discussion is helpful to the original post.

From the AT-897Plus manual:
"...When the transceiver is turned on, the AT-897Plus powers up [and] checks the connection to the transceiver. If this check fails, the Status LED will blink continuously. Possible causes for failure are an improperly seated CAT cable, a damaged CAT cable, incorrect CAT baud rate setting, or plugging the CAT cable into a radio other than an FT-897 or FT-897D."

Does this happen when the computer (and HRD) are not connected to the AT897's CAT through-port? FT-897 CAT data rate set at 4800?

Topic: 7397 Message: 7397

They say that Collins will no longer manufacture those wonderful mechanical filters that so many of us

love after the imminent, and limited, final production run. Seems that DSP technology and the

concomitant ever dropping cost has finally doomed these fine Collins products after over 65 years

since their introduction. In case you are not aware, it takes about 12 weeks to manufacture one of

these filters!

Those of you who own the FT-817/ND, FT-857, FT-897/D, FT-1000MP, Field, & Mark V, FT-2000/D, IC-703

(Plus), IC-718, and so on should consider seriously if you don't already have the filters you want, to

go ahead and purchase them while these filters are still available (and the prices have not risen

yet). Collins says that when they are gone, they will be gone forever.

If you want these filters, check with www.w4rt.com, www.gigaparts.com, www.hamradio.com,

www.aesham.com, etc. All of these organizations also offer the dual CW/SSB filter for the FT-817 made

by W4RT Electronics.

As a personal observation, I have used Collins mechanical filters since 1960 and I have never found a

DSP-based filter that produces that special "sound" you get from the Collins filters. They will be

missed, I am sure, by many of us.

I had a failure with my AT-1000ProII purchased June 2013 where it wouldn’t tune my 80 meter dipole plus there was a “hot” smell coming from the tuner. Under warranty LDG replaced 2 caps and a bifilar inductor which corrected the 80 meter problem. From new and after the repair this tuner has had an issue tuning 6 meters with two antennas which the internal autotuner in my Yaesu FT-450D will tune (that tuner only matches 3:1 or lower). My LDG Z-11ProII also tunes these antennas easily on 6 meters. I don’t run power on 6 meters and in fact almost never use 6 meters so I never really cared how it performed since I have the other two tuners to fall back on. If I keep punching buttons it seems that at some point the tuner will then tune the 6 meter antennas but I shouldn’t have to coax it that way. Now, in all fairness, I never advised LDG of this issue so I don’t know if it is a design constraint or some component out of whack from new. I hammered this tuner last year in pursuit of the ARRL Centennial WAS Award and other than the issue with 80 meters it has performed well and is still performing well. I wouldn’t hesitate to buy another LDG product.

Subject: [LDG-auto-tuners] T-1000 Pro II w/ M-1000 Meter

First, I want to say that I am very happy with my older AT-1000 Pro Autotuner. I have had nothing but good luck with this tuner and still use it today.

I purchased a new AT-1000 Pro II with M-1000 meter in November of last year to work with my TS-2000, ALS-600 Amp, and DX Engineering DXE-MBVE-1 43 FT ground radial antenna w/ 4:1 UNUN. Because I already owned an older version and it worked so well, I decided to purchased a newer model, taking the advice of a DX Engineering staff member. The tuner worked great until a few months ago. I t would not manually or auto tune my 43 FT vertical but when replaced with my older AT-1000 Pro, everything worked great. I sent the new tuner in for warranty repair and this is where my troubles really begin.

After waiting a very long time and no way to contact LDG (didn't answer their phone or emails), I vented my frustration in this foru m and several members explained how busy LDG was and that they were a small company. I understand because I once had a small company that kept me very busy reprogramming vehicle's ECUs. A week after my discussion in the forum, I received my repaired AT-1000 Pro II from LDG. The service ticket stated the unit does auto tune but wasn't finding the best matches so Mr. Kincaid realigned and calibrated the SWR circuit.

I installed the repaired AT-1000 Pro II with my TS-2000. I didn't hook up the ALS-600 Amp because Mr. Kincaid made a remark on the repair ticket for me to read the operational manual and that the amp was most likely the cause. This wasn't the case because I had tested the questionable tuner on my other transceivers and various other antennas and it still wouldn't auto or manually tune. My older AT-1000 Pro was installed and worked

perfectly every time.

I am at a crossroad with LDG and their products! This new tuner in not as good as my older one and quite frankly, their warranty service has been less than desirable.

Has anyone else had problems with their new AT-1000 Pro II Autotuner or am I the lucky one who has a new AT-1000 Pro II that doesn't work and can't get LDG to fix it correctly?

Frank

Hello Mike,

We do not have an interface cable for the AT-1000ProII and the FT-3000 at this time. We're testing one now and may have something in a couple of months.

Yes - I bought one. Waited a long time for LDG to develop this remote 600W tuner. It works great BUT with one MAJOR drawback. LDG RT-600 claims to have 2000 memories and that maybe correct, but the RT-600 Autotuner does not retain any of those 2000 settings once the power is removed. This I am informed by LDG Repair is because the RT-600 does not have any latching relays. Minor oversight - but should be included in the advertisement. I was expecting an autotunes with 2000 memory locations to work like every other auto tuner with memories and retain those memory settings for each frequency. Definitely lowered my opinion of LDG on the whole. SO if you are content to RETUNE every time you use this tuner on different frequencies because you removed power from the RT-600 then it works great. I would be hesitant to recommend the RT-600 for this reason. Bruce/NN4BJ

The manual (I don't have this tuner) says it consumes 7 ma in standby, which suggests an added memory battery could overcome the lack of latching relays for some users.

I just jumped in a made a comment without doing any research. I just went to the LDG site and viewed the manual. Unless I missed something in this thread doesn't this excerpt from the manual cover the concerns; "In this manner, the RT-600 "learns" as you use it, adapting to your bands, frequencies and antennas. The RT-600's latching relays hold the tuned configuration indefinitely, even when DC power is completely removed. Tuning memories are stored indefinitely in non-volatile flash memory"?

Just a comment here…latching relays only maintain the last tuned frequency and possibly make the next frequency tune occur more quickly. It is the memory in the unit that stores the settings. I think that Cortland has a great idea.

According to the email reply below I received from Dwayne Aug 3rd 5:30PM - the manual must be wrong. I'm still awaiting a response to my original question and service request. It appears to me the remote tuner is not remembering the settings when I return to a previously tuned (i.e. memorized) frequency. I'll try this all again when I get my loop back up in the trees and hopefully the tuner I received back from Service will function properly, even though the tech stated there was nothing wrong with it. Hello,

No, the RT-600 does not have latching relays.

The same freq no tuning is so the tuner does not continually search if no match is found.

Yes, we check the memory first before retuning. Reducing RF power may help tuning from memory.

The tuner will remember settings for frequencies. However, you cannot memory tuner form the same frequency more than one.

My Tuner has stopped tuning completely. When I transmit in either SSB or AM, none of the LED's will light up. Plus I get no receive on the radio. If I put it in Bypass the receive audio comes back OK. I have a Flex 6300 and the Panadapter verifies the audio issue. When in Bypass I can use the radio's antenna tuner and it works as designed. My question is: by chance is there anything I can do internally on the tuner or is this unit destined for the shop?

Hi
I had someone look at my faulty AT-100 PRO and they found a faulty relay. We cannot seem to find a replacement here in the UK, the details are: FRT3-SL2 DC 9v
Is there an equivalent part number for this relay?

I have emailed LDG in the USA for help but if anyone knows where I can obtain this in the UK I would really appreciate it.

Thanks.

New here so not sure if this has been covered. Has anyone used the AT-100 PRO II for ALE? I use it for both amateur radio and CFARS (similar to MARS in the U.S.). It works fine except I need to be able to get the BYPASS to engage during radio scanning so my rig hears each frequency without the tuner staying set on just one of them. I use a SignaLink USB external sound board for a controller using MARS ALE (hams in the U.S. have to use PC ALE due to their regulations).

I asked LDG and they referred me to this group.

I have the PRO 100 and the bypass can be engaged from the front buttons. However, mine will not stay in bypass when it sees a carrier. It goes to auto tune with RF. I looked at installing a power on/off switch but room on the back panel is limited however a small DPDT toggle can be possibly installed for scanning with power off.

Hi Lawrence,

Dwayne sent you to the right place.

See:

The RHUG Appendix B .pdf that is distributed with MARS-ALE v3.0 and also see:

http://www.n2ckh.com/MARS_ALE_FORUM/ldg_radio_port_DTR_reed_relay_circuit.jpg

In the MARS-ALE RHUG Appendix B comments on the
LDG PRO series selection for ATU types in the pull down menu it states in part:

"This selection specifically supports LDG PRO
models via the "Radio Interface" port on the rear
of the ATU for placing the ATU into BYPASS during scanning.

The ATU re-enters ACTIVE mode by the application of RF.

It is recommended that an ☐ATU Tune Words☐ setting of 1 be used to generate
the required RF tuning signal to re-enter ACTIVE
mode for ATU memory operation.

The DTR line of the selected serial port is used
to select BYPASS via user provided interfacing
circuitry (see Figure 1. below) where the DTR
line is held high for 100ms. To achieve BYPASS.
The 100ms. Is the default value which can be user
entered via the MIL-STD-188-141 options dialog to
the right of the ATU Comm Port selection (a range of 10..1000ms is accepted).
NOTE: The use of ALE TUNE Words on the ☐188-141
Options dialog set to 2 or 3 is required in
support of this class of ATU models."

So basically just make the circuit and attached
it to a serial port or use a USB to TTL
experimenter board with a DTR line. Then select
the LDG PRO as the ATU type and the serial port
and then you need to enabled CAT ATU on each
channel in your scan group using Channel Modift
where you need the use of the ATU.

Hi Lawrence,

Regarding your comment, HAMs world wide use PC-ALE vs. MARS-ALE and
for free. MARS-ALE is a licensed tool to EMCOM entities directly
supporting Government and Military such as MARS, CFARS, U.K. Cadet
Corps. etc., any NATO country. Also any North American Amateur Radio
EMCOM group can license it as well. There is no cost for MARS-ALE either.

MARS-ALE and PC-ALE are very different being focused on different
user requirements and being completely separate baselines. However,
it is planned that when PC-ALE v2.0 debuts, it will be generated from
the MARS-ALE baseline, with more features in common, such as this ATU
support you have queried and PC-ALE will still be uniquely different
in that some features enabled for it will not be enabled in MARS-ALE
and a host of features enabled in MARS-ALE will not be enabled in PC-ALE.

Dr. Don,

The AT-100Pro or ProII will tune anytime the SWR is above the set Threshold when in Auto mode. Either increase the Threshold or put the tuner in Semi mode.

If you are getting re-tunes from RF on the DC power supply, add RF chokes to the DC supply to the radio and to the tuner.

Thanks Dwayne. Yes I use the semi mode often. Particularly when driving my SB200 on 40 meters.
The problem I referenced is when I put the PRO100 in bypass and then apply RF it starts to tune.
I will try a isolated DC input.Perhaps then it will stay in bypass.

I wonder if you have had any success with it on the 6300?
I just purchased a 6300 and a used AT1000ProII.
My 6300 doesn't have a tuner in it.
The 1000P2 is really not working very well yet with my 6300.
Seems I have SWR sometimes on most all bands of 1.2 or so, but then switching from say 17M to 15M the SWR flipflops. That is one time it is 1:1 on 17M and 1:1.7 on 15M. If I do a manual tune on 15M then it does go to 1:1 but 17M then goes to 1:1.7 ? and Vis versa.
I'm wondering if I should be sending the 1000P2 to LDG?
I emailed support and got a goofy answer.

A 1.7:1 is NOTHING to worry about. The antenna tuner is set to hunt out a 1.7:1 or better SWR. Honestly, a 2:1 is not really that bad, though few modern rigs like it, but a 1.7 is not going to get any rig upset, and is nothing to worry about. Long as you are making QSO's, I would not worry. Even with a tuner, a "perfect" 1:1 is almost impossible.

From: k6whp@...
Topic: 7431 Message: 7431

Wanted to verify that the Z11 Pro II does not seem to work 100% with the IC-7200 while it will function with the IC-706 MKIIg. When hooked up to the 7200 with the stock cable, mine come up with the two middle LEDs lit and not function any further despite the function buttons being pushed. Needless to say, the 7200 TUNE button does not function while the 706 does.

I have two Pro IIs and tested then on both my IC-7200 and mi IC-706 MKIIg. Neither works on the 7200 and both worked on the 706.

Appreciate any help.

Bill, k6whp

Let me put this another way: has ANYONE here used a Z11 Pro II with their IC-7200 and have it work as it should? That is, pressing the "TUNE" button on the IC-7200 puts the LDG into the tune sequence?

Thanks in advance.

Bill. k6whp

Hey Bill,

My last radio was the 7200 and I used the z11 tuner with it. Mine worked no problem, just like you said, by pushing and holding the tune button on the radio until the z11 went into a tuning cycle. In order for it to do that you do need a special cable. I don't remember the item number for it but it is the cable that goes from the 4 pin flat connector that fits into the back of the 7200, to a split tipped deal on the other end. One tip is the power that goes into the back of the z11 and the other is an 1/8" jack that also goes into the back of the z11. You need that cable to power the tuner from the radio and for it to communicate with it. Otherwise pushing the tuner button on the radio won't do anything. If you search for the z11 tuner maybe on HRO and look at the accessories available for it, you should find the cable I'm talking about. Hope that helps.

Chris,

Thanks for the response and sincerely appreciate the input; here are some facts:

(1) I have TWO Z11s and TWO sets of cables. (Cables as you described. Commercial; not home-brewed.)

(2) BOTH function correctly on my IC-706 MKIIg. (I even interchanged the cables with the Z11s.)

(3) BOTH function incorrectly on my IC-7200. (Ibidem.)

(4) BOTH malfunctions exhibit identical symptoms:

(a) Plugged into radio.
(b) First Z11 outboard LEDs light up.
(c) After one second (or so) the outboard LEDs go out and the inboard LEDs light up.
(d) The Z11 is "frozen" -- does not respond to button pushes, etc.
(e) Needless to say, the TUNE button on the IC-7200 doe snot function.
(f) When "radio control" plug (the phone plug) is unplugged, the tuner functions manually as designed.

(5) I did a cursory inspection of the cables and found:

(a) Pin 1 of Molex -> Pin 2 tip
(b) Pin 2 of Molex -> Pin 2 ring (+4V to collar or pin 1 outside)
(c) Pin 3 of Molex -> Pin 1 center (+12V to collar or pin 1 outside))
(d) Pin 4 of Molex -> Pin 1 outside (gnd)

Note that the above was only cursory; will go back and confirm.

(6) IC-7200 settings:

(a) PTT TUNE - "ON"
(b) ANT TUNE - "ON"

(7) Leads me to believe it's the IC-7200 -- for some reason. ("Hmmmmm. No fooling?")

(8) Dwayne at LDG could provide only "our IC-7200 had no issues with our Z11" so I also will be researching the LDG Interface Application Note that describes the interface in more detail as well as any data in the nature and behavior of the IC-7200 tuner interface.

Again, appreciate any empirical experiences and insights proffered.

Will report back.

I see the problem. (4) (b) should be: Turn on radio. Two reasons. One, if you plugged the tuner into the radio with the radio on, you probably have damaged the radio. Second, the radio only looks for the tuner once when you power on the radio.

Dwayne,

Thanks for the input; you may be correct and, if so, it is troubling. (I hope I have not glitched the radio. One would think that Icom would have made the interface tougher than that.) I still get the aforementioned +12V and +5V at the pins described so I am hopeful.

Shamefacedly, I cannot recall plugging the Z11 in and THEN turning on the radio -- although I am sure I must have. I wonder what Steve, the other gentleman who was having similar problems with his LDG tuner has done.

Anyway, thank you for your response; I am studying your app note and the info on the IC-7200 plug and will resolve it somehow.

72,

Bill

Hi Mike

Take a look at the three pdf in the files section.

1. -FT3000_Amplifier_and_Tuner_Keying.pdf
2. TunerInterfaceAppNote.pdf
3. MeterProtocol.pdf

On the first pdf only look at the schematic for SW2.

I have made my cable from the tip and ground on a 3,5 mm. minijack to pin 11 and 15 on the linear connector on FTdx3000.

Tip to pin 11 and ground to pin 15.
Remember to change menu 178 to 10 W.

Then when you press the tune button on the LDG tuner, the FTdx3000 send an carrier on 10 watt and initiate a tune cycle. It's working perfectly.

To go futher on, you can buy or build your own USB cable according to the pdf file MeterProtocol.pdf and then control your tuner via. software.

..well, Dwayne, finally scraped out some time (got slammed at work last week) and boy do I feel the fool! Of course, I missed the obvious at first but when I followed your advice, it worked just fine! It was like an engineer who crawls all over his device performing all the exotic tests and measurements and them while scratching his head, he notices the damn thin is not plugged in to the wall socket.

This, of course, was my case almost literally. (Glad to know also that I did not fry the radio!)

A recommendation to others here (aside from ensuring that you don't overlook the obvious) would be to download and review the write-up on the LDG site re the tuner interface. It provides a good understanding as to what goes on.

Thanks again for the advice and the patience, Dwayne!

Dwayne,

Thanks for the input; you may be correct and, if so, it is troubling. (I hope I have not glitched the radio. One would think that Icom would have made the interface tougher than that.) I still get the aforementioned +12V and +5V at the pins described so I am hopeful.

Shamefacedly, I cannot recall plugging the Z11 in and THEN turning on the radio -- although I am sure I must have. I wonder what Steve, the other gentleman who was having similar problems with his LDG tuner has done.

Anyway, thank you for your response; I am studying your app note and the info on the IC-7200 plug and will resolve it somehow.

72,

Bill

7448. AT600PROII Bypass LED

7449. Z11 Pro II not tuning on 40M anymore

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-09-07 14:28:51 UTC
From: ea5125ure@...
Topic: 7449 Message: 7449

Hello,

Its been a rainy couple of weeks and I had my longwire with unun exposed to the elements in a more or less harsh weather, daily. The transformer is 1:9, and the connected enameled copper wire is around 30-40 meters perhaps.

My antenna analyzer is giving me these readings:

FREQ SWR Z
1,800 >10 241
3,700 4.20 14
7,100 7,97 30
10,100 3.82 133
14.100 4.93 66
18,100 3.81 141
21,000 2.60 61
24,900 4.67 17
27,000 2.34 48
29,000 4.35 37
51,000 9.81 241

For 40M I get 7.94 8-j28. The ranges of inductance/capacitance and SWR/impedance are all well within the specs of my tuner. However it is giving up on 40M, after a while (I see the green light flashing up several times and so does the yellow, so at some point it might be getting a <2.0 SWR tune).

I have just checked the unun and it is dry and good as new. It is self-built and I have yet to have toroid saturation problems, or over heating, or water ingress (or egress from condensation).

I am about to test my coax but I doubt it is the issue.

What could be happening? Is it a potential relay problem? Toroids inside the tuner look fine. Unfortunately the relays aren't clear plastic cased, so I cannot see inside. Nothing appears to be wrong.

What makes the tuner 'give up'? Can this be altered in any way? (three left most lights flashing).

I will check the longwire later.

Thanks!
73

Do you have any "Before" readings with your analyzer?

First thoughts are that you have a bad connection, or something is
laying across the antenna wire.

Joe

I have had the LDG Z11 Pro II for two years now. The good news is that it will work. It will tune an antenna. The bad news is that it takes too long to tune. I use it only for out door portable use. And always attach a 16 foot antennas (wire or whip) to the tuner. I work mostly 20 meters. If the band is good I will also work 17 meters. Never 40 meters.

The Z11 Pro II take 20-30 seconds to tune any antenna. I worry about my finals, even though I tune on low power (5 watts). I have always thought this too long at time to take to tune. My MFJ-993 takes about 7 seconds to tune the same antennas (at home). While my new Elecraft KX3 internal tuner takes 2 seconds flat and will tune any length of antenna that quickly. The Elecraft tuner has me thinking. Why does my Z11 Pro II take so long to tune?

My Z-100 takes about 10 to 15 seconds to tune most antennae. On 80 meters at home it takes quite a while, but it's probably because of some weird combination of Resistance and Reactance shown to it by my balun and window line feeders. I could fix that by adjusting the length of the feedline, but I haven't gotten around to it for the past 8 or 9 years.

In the field, I typically use slightly more than 35 to 38 feet of wire, supported by a 31' jackite pole, and a 31' or so counterpoise, either supported on a chain link fence which is at one of my favorite operating places, or on the ground if I'm elsewhere. I've found that 31 feet of wire is a bit too close to 1/2 wavelength on 20 meters, so lengthening out a bit is a big help. I can tune it with the Z-100 on 40/30/20/15/10 meters. If I want to operate 80 meters I need to wrap about 30' of wire on a piece of plastic drain pipe

You didn't say what kind of ground system you are using. I generally use a balanced feeder at home, or counterpoise, as described above when I'm on the trail. But, if convenient, I pound a 3 or 4 foot ground steak into the ground and use that as a 'real' ground,

Hi folks. I am a lover of 20 meters, have been since I got licensed in 1979. Also enjoyed 15 and 10 before WARC, but 20 has always been my workhorse.
The other day I fixed my 20 meter dipole (turns out it was about two feet too short, and also had a short), put on RG-59 (I had RG-8x from Radio Shack, but there was a short somewhere - Tandy Cable is NOT what it used to be!) which I had lying around, hoisted it up, and got a 1.5:1 SWR, which in this Old Timer's opinion, is perfectly acceptable (most of my rigs in the past were tube type). I played around with it, checking it against my 102' doublet (ladder line to the shack, to a 4:1 balun), and found it to be OK, though the doublet, an MFJ-1777, is directive in places. Worked a couple of DX contacts, then saw on DXwatch.com that a J68HZ, St. Lucia, was on 17 meters. My tuner, an LDG-AT600Pro II hates 17 on the doublet , and will not tune it, though tunes everything else just fine, including 6. I switched to the 20 meter antenna, and lo and behold, it tuned the 20 meter antenna to less than 1.2:1!
Being an Old Timer, I was reluctant to use an antenna on a band it was not cut for, but did it anyway.

Now, the antenna is resonant on 20, at about 14.200 or so, on the Advanced/Extra portion of the band. I thought "what the heck" and loaded the SB-200 (yes, it will load up on 17, and also on 12 - probably on 11 if I wanted, which is NOT likely!) to around 500 watts, and called, and BROKE THE PILEUP!!!

My curious mind asks "how did I do that"? How did I use a non resonant antenna through a matcher, through 30 or so feet of coaxial line, and still get a good signal out? I wonder how much I lost in the process?

Oh, St. Lucia was a new country for me!

I have owned many LDG tuners over the years and never had any issues.

I recently purchased a nearly new 817H tuner which works perfect apart from having had something stored on top of it that has scored the top of the case down to the metal. Doesn't bother performance but not nice to look at.

A quick email to Dwayne to check in the availability of spares resulted in the fact that cases are not standard spares but they would have a look around for me to see what could be found.

A couple of weeks later and a box arrived at my home address with a new top case enclosed - FOC !!

This would have been excellent if I was in the States maybe, but it's truly outstanding as I'm in the UK.

Many many thanks Dwayne & LDG outstanding customer care and support

I have improved the ground (three 6 foot ground rods, connected with 1.5 inch copper strap, 8 feet apart). I have used single point grounding in the shack, antenna cables come in the shack into grounded polyphaser lightning protectors (all common ground) and still the same issue. The rig's internal tuner works fine but the at-600 proII still gives me the loss of rf and won't tune.

Today I have sent the unit back to see if there is something wrong with it :(It's a frustrating problem, I'm almost hoping there is something wrong with the unit, because I don't know what to try next other than a manual tuner.

Just recently (last 2 days), my AT-200Pro II has had trouble tuning my G5RV for MARS freuqencies. It goes through the sequence and when it stops I still have a high SWR. It has previously for several months, tuned with no problem. I've checked my antenna and there seem to be no problems. I am still able to tune the HAM bands with no issues.

Any suggestions? Is there a way to "clear" the memories to start over?

Thanks and '73

Topic: 7462 Message: 7464

Hi Jim,

There is nothing as far as the ATU itself is concerned that is
different between HAM vs. MARS frequencies.

I would suspect your G5RV has changed in some respect if the channels
for MARS use are the same ones that you have previously used with no
issues tuning.

The G5RV type antenna is not a use on any MF/HF frequency antenna,
there are many spots across the spectrum that you just will not be
able to tune it.

One make of GR5V due to design approach and the arrival of 60 meters
years ago published with the antenna not to attempt use at all on
5Mhz, that was Van Gordan. It was useless for any use across 5Mhz,
could not use it for HAM or my MARS or SHARES needs in the part of
the spectrum or on some other discrete frequencies here and they.

Should you have or can borrow an Antenna Analyzer you can determine
at a quick glance the antenna's current characteristics. If you have
done so in the past and recorded them, you will be able to note any
change. Depending on the physical design, you may need to address
some wear and tear on the antenna. I have had squirrels in the past
nibble on coax as they munched their nuts while resting on my feed
lines back in NJ... hi hi Here in WNC its just ladder line and
radiating wire that I have strung out as coax is a short run to
mounted RF transformers, they don't like perching on either.

I have the same tuner, and most of the time I can tune my antenna quicker using my old manual MFJ-949 tuner. That's once I have operated a frequency and written down the tuner settings and can refer back to them next time I use that frequency. With the MFJ, I just set it to my logged settings then check and tweak it with low power. I agree that the LDG takes waayyyy too long to tune in most cases. Even my Icom AH-4 and SG-237 autotuners are lightening quick when I use them ! My LDG has been relegated to a backup tuner and occasional field tuner.

From: ldgyahoo@...
Topic: 7467 Message: 7467

Hello All,

Just wanted to send out a feeler to see if anyone is using the Icom RS-BA1 software? This software allows control of an Icom radio over the internet.

I noticed the other day on the Icom page that the software has a mouse clickable Tuner enable button and a Tune button in the radio display. In theory, that would allow you to control the tuner remotely. If it really does work like that, it’s possible that it would also control an Icom external tuner.

Then, reaching even farther, since the radio detects the external tuner on power up and the control software may also control the external tuner, it stands to reason that it would also control any LDG tuner that we have that interfaces to the Icom external tuner port.

Technically, I’m not sure how they would do it since there are no tune commands available in the CI-V protocol. Perhaps the tune control has always been available, but those parts of the protocol were never published.

There is not a ton of info available about this software on the Icom web site, but it says it works with just about any fairly recent Icom radio (7851, 7850, 7700, 7800, 7600, 9100, 7410, 7200 and 7100) and also older ones by using an additional cable (756ProII,III, 746Pro, 7400 and 7000).

If this works like it shows on the user screen, this would solve a ton of problems for those that want to install a remote station using Icom radios.

I use a LDG AT-100ProII with my Icom IC-7000. It may take a little long (seems like) to tune, but my MFJ-993B takes about as long.
I use a LDG AT-600 Pro II autotuner with a SB-200. If I have EVER tuned up on that frequency before, it tunes right to it. About 1/10 of a second. If not, it has to "hunt".
It is well worth what I spent on it.

I was using a Heath SA-2040 with a balun. I had to:

1. Roll the big roller inductor to the neighborhood.
2. mesh the "ant" cap to the correct place (we hope)
3. tune the "trans" cap to the "dip" on the SWR meter.

Even if I had the settings written down, it could take some time. If not, OMG! It could take a WHILE.

With either LDG, if I have ever been there before, I hear "clung", and it is tuned. If not, it may take from 3 to maybe as much as 10 seconds.

When chasing DX, a few seconds can make a big difference!

Hi just purchased a LDG YT-847 Autotuner and cannot get it to work with my Yaesu FT 847.
When I press the tune button on the YT i get an ERROR message on the screen.
Also I cannot go into transmit,get the ERROR message and the FT 847 stays in the receive mode.
Any help please.
Peter.

I have a AT-100ProII also and operate ALE with the Canadian Military Affiliate and find the tuner doesn't seem to do as good a job of memorizing. I manually go to each channel and force a tune, which should 'memorize' it. When ALE scans and sounds most of the low channels try to retune. The delay caused by retuning means my transmission is usually not heard. The solution is to buy the spiffy computer connected ATU which is no longer available. The other fix is a T2FD similar to our military setups which do not require a tuner.

The attraction of LDG is they operate up to six meters which none of the MFJ units do, and therefor a nice match for my FT897. The tuner the way it is set up is not ALE friendly and others in our team have similar or identical products and have the same frustrations.

We have an upcoming joint exercise with the US, UK and Aus/NZ and will have substantially more frequencies in play than our CFARS/MARS groups. A solution would be appreciated.

I know something about how the LDG firmware works and can assure you it does not favor one band vs another regardless if ham or other. I purposely fashioned it to meet all applications, including yours. Is your antenna hi Q (narrow/sensitive tune) at the frequency of use? What frequency are you using?

The antenna is a 135' OCF with 4:1 current balun and oriented away from my house. Our normal frequencies are located near the band edges of the ham bands for 160 through 10 metres. The exercise frequencies will be assigned from a pool of the various countries participating. Unfortunately most of these are classified. On amateur I use the HFN block of frequencies with some bypassed as possible high SWR has been affecting my main computer. The station is well grounded and I am located right beside the city water line for bonding.

Try tuning in a few areas of the bands of interest so it can learn the antenna more. The memories are closer together the lower the frequency as antennas are typically higher Q at lower frequencies (especially shortened antennas) and are fewer up higher. As I noted before there is no band edge detection, it is a continuous algorithm.

7475. AT-600ProII

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-09-27 02:52:07 UTC
From: chipmckcmo@...
Topic: 7475 Message: 7475

I have a 600ProII tuner connected to a Yaesu 897D. Pressing the tune button on the tuner does not begin a tune cycle, no RF error message appears. The red end of the cable is in the ACC jack on the radio and the black end is in the radio jack on the tuner. It appears that either the 897D is not accepting the tune signal from the tuner or the tuner is not sending the tune signal. Is it possible to measure the signal from the tuner at the radio end of the cable with an OHM Meter? I was told that here are no menu changes necessary on the radio for the tuner to operate. By the way, the Y-ACC cable is new and I did check the cable for proper continuity. The only two things left are the tuner or the radio Interface or menu settings.

What do you think?

Chip

Hi chip
I think you may still have to put the radio in to tx your self as it is a simple cable you have

With that cable I think it makes the radio just give a tone
I may be wrong

I too bought the cable for my FT-857D but I haven't tried it yet. nor have I read about anything that needs to be done to the radio.
My belief is with the cable attached when the tune button is pushed
on the Tuner it sends a signal to the radio to go into the AM mode
reduce power and tune the set frequency. I will try mine next week
Hope it works
LARRY KB8EMD

I can tune up, although not always successfully, inside the ham bands. 14.110 is ok, 14.109 is higher SWR and wants to retune. Obviously as the military frequencies are channelized transmitting on anything other than assignment would get me in hot water.

The OCF is being re-configured to inverted V once a higher mast for the feed point is installed and cable is buried back to the house. I doubt I would consider a remote tuner except for a vertical. I like being able to see the SWR conditions as I operate and I'm not sure how I would know if the remote tuner was re-tuning.

Another thing to try is reduce the power during tuning. Try 25W or even lower and see if that helps. If it does, it may be an indicator of RF in the shack. If tuning at a lower power works, as a stop-gap measure, turn off the automatic tuning per the user manual and tune at low power until further troubleshooting ultimately solves the problem.

I generally tune my Z-100 with 3 to 5 watts. Instructions for my Z-100 say to lower power to below 20 watt for tuning, and that it will tune as low as 1 watt, though I find it works best with 3 to 5 watts. Specs for the Z-11 say it may take up to 6 seconds to tune, so if it doesn't tune within 10 seconds or less, there's either RF in the shack (as said below) or something is wrong with the processor or programming thereof. If you can find a dummy load with 300 or 400 ohms resistance, so you'll have a high swr load, try matching the dummy load and see if the tuner works properly. If it does, that would indicate RF in the shack getting into the tuner.

The tuning on all LDG tuners is continuous from 160 through 6. My At 600 does not like 17 meters on my 102 foot doublet for some reason, but loads the 20 meter dipole fine!

Larry, Please let me know when your cable arrives. I would be interested to know if it works as an auto tuner. The radio manual pretty much says that the radio responds with a low level transmit signal while the tuning process is in progress.
Thanks,
Chip (chipmckcmo@aol.com)

I've dealt with RF most of my life from almost DC to daylight and proximity to the antenna, good grounding or not causes strange things to happen. A combination of line lengths, antenna placement and weather can have an effect. The station is well grounded.

This is probably not an ideal combination for ALE. Once the tuner is set for a frequency it has a positive influence on receive signal. But considering we are scanning from 2-5 channels per second the tuner is not optimal until it detects RF and switches to the stored setting. The trick is forcing the tuner to go to bypass after returning to scan. The ALE software was designed to work with a serial port (long gone) and I have to figure a way to accommodate a line from a USB adapter as well as the tune line between the FT897 and the AT100. Relay closure time dictates tune of bypass so they should be able to be combined on the same line.

There are single ICs that convert USB to RS232 that support the handshake lines. Many cables on Amazon or ebay us this chip that is well supported....

http://www.ftdichip.com/Products/Cables/USBRS232.htm

With the VCP (Virtual Com Port) drivers it shows up as a Com port in device Mgr.

Bought the Y-ACC cable for the Yaesu FT-857D and the LDG AT-200
when I push the "tune" button on the tuner it seems to tune goes into bypass mode
but will not pass any signal from the FT-857D when I transmit.
I have tried AM-CW-SSB none shows on the Tuner as being transmitted
If I turn off everything and wait for a short amount of time I can transmit and the LEDS on the Tuner light like they should. It would be nice if all I had to do was push tune like it says I should be able too.
Anyone have an ideas on what is happening and how do I fix the problem?

Thanks Larry KB8EMD

I did I've checked it several times
I read LDGs web site it says pushing tune places radio in CW mode
When I manual tune I have to use AM mode
I'm wondering if placing radio in cw mode is the cause.
Although the Mike wont cause the radio to transmit in CW maybe the tuner doe .
I just don't know because it seems to tune.

Larry:
Pushing TUNE quickly will get you into bypass mode, pushing for more than 1 sec but less than 2.5 seconds does a memory tune. Pushing TUNE for more than 2.5 seconds should force a manual tune. You may have to activate PTT unless the special cable does that for you.

Brian thanks for the tip about tuning

I have used the tuner in the fashion you mention while transmitting in AM mode,

the FT-857D PTT does not transmit in CW mode only AM and maybe other modes as well.

The Y-ACC cable is supose to place the radio in CW mode and tune, which it does seem to tune
but always ends up in BYPASS mode and then it won't pass any form of transmitting mode.

My old FT 757GXII will transmit in cw by using the PTT it also has a transmit button and works well
with the LDG tuner.

I have not tried my Z-100 yet I will try sunday to see if it works, I would like one button tune.

Yaesu will not transmit a signal in cw mode when keying the mic. You have to have a cw key.

Also, the AT-200 does not interface with the 857; LDG makes a tuner for that rig.

It will auto tune if you set the menu for 10 watts AM. Turn to AM to tune, then go to SSB.

Alex, the 200 tuner is a generic tuner as is my Z11proII and both use a cable from the rear port marked "radio" and the other end goes to a Yaesu radio if you use or make the appropriate cable. See page 14 of the AT200 tuner at the LDG site. When you press tune on the tuner it puts the 857 into a cw mode and the tuner goes thru a tune cycle. When you release the tune button the 857 reverts to the mode which you have selected. I don't know why you said the AT200 does not interface to the 857.

You hit the nail on the head when you mentioned holding the tune button for a longer time.
Today I tried both Z100 plus and the At200 pro both worked great as long as I held the tune button just like I do when tuning manually.
The radio went to a lower output and tuned great.
When one understands the how to
things work great.
I hope my not knowing and asking you guys for help
Will help someone else. Thanks

The tuner does not interface without a cable. If the operator has the cable, he can RTFM and get the data on menu settings for the LDG AT-200, set them, and away he goes.
Unfortunately, my FT-950 will not interface directly with any LDG tuner except the 450 and 1200 tuners. I got a AT-100ProII and used it for a while with no cable interface (I now have an IC-7000 hooked to it). I now run it to an AT-600Pro II autotuner, and it also has no cable interface for the 950.

I do not understand why LDG cannot make a cable interface for their tuners (other than the YT-400 and 1200) that will work with the 950. MFJ makes one that works with their 993B tuner, and my IC-7000 has a short cable that works either the LDG /*or*/ the MFJ.

Yes, the 857 will work with the tuner, but you can't simply tune to CW; it has to have the interface cable which is seen here: http://www.ldgelectronics.com/c/252/products/19/24/1 then you can simply push one button.

With the 950, you have to set it for 10 watts on AM, switch to AM, press PTT, the tuner tunes, then press the SSB, and you are on the air. Takes only a second or two when you get used to it.

D's
A
Dave
I have the FT-857D I use a Y-ACC CABLE THAT PLUGS INTO THE ACC port on the radio and into the back of my Z100+ into the radio port.
The cable does not supply voltage I either use batteries or an external power supply.
I did just learn that the way to use the tuner hooked this way I can push the tune button on the tuner and the radio will go into CW mode and transmit at a lower power tune the antenna and switch back to what ever mode and power setting I was using.
When tuning you hold the tune button in just like you were tuning it manual
Since I learned how to do it right it works great.
The Y-ACC cable works with the FT817
LARRY KB8EMD

7509. Re: [LDG-auto-tuners] Re: interface cable for the Yaesu FT817ND to the LDG Z100+

Thanks Larry

The Z100 and the LDG are different connections for the Auto Tune

I've recently acquired a second Z100+ from a silent key sale and was hoping to hook that up to my 817

I know I'll have to sort out different connection cables

At 70++ my soldering skills are not what they used to be ;-((

But thanks

David (G8UVE)

Is this for the 950? If so, I may be able to work my AT-600ProII! Tell
me how?

Actually, it has an external tuner port, and the MFJ tuner thingie uses it. Right now I have a Ameritron ARB-704 attached to it, so I can not use the tuner port. The ARB controls a SB-200.

Subject: Re: [LDG-auto-tuners] Re: Yaesu FT-857D and LDG AT-200pro

The tuner does not interface without a cable. If the operator has the cable, he can RTFM and get the data on menu settings for the LDG AT-200, set them, and away he goes. Unfortunately, my FT-950 will not interface directly with any LDG tuner except the 450 and 1200 tuners. I got a AT-100ProII and used it for a while with no cable interface (I now have an IC-7000 hooked to it). I now run it to an AT-600Pro II autotuner, and it also has no cable interface for the 950.

I do not understand why LDG cannot make a cable interface for their tuners (other than the YT-400 and 1200) that will work with the 950. MFJ makes one that works with their 993B tuner, and my IC-7000 has a short cable that works either the LDG or the MFJ.

Yes, the 857 will work with the tuner, but you can't simply tune to CW; it has to have the interface cable which is seen here: http://www.ldgelectronics.com/c/252/products/19/24/1 then you can simply push one button.

With the 950, you have to set it for 10 watts on AM, switch to AM, press PTT, the tuner tunes, then press the SSB, and you are on the air. Takes only a second or two when you get used to it.

[LDG-auto-tuners] wrote:

Alex, the 200 tuner is a generic tuner as is my Z11proII and both use a cable from the rear port marked "radio" and the other end goes to a Yaesu radio if you use or make the appropriate cable. See page 14 of the AT200 tuner at the LDG site. When you press tune on the tuner it puts the 857 into a cw mode and the tuner goes thru a tune cycle. When you release the tune button the 857 reverts to the mode which you have selected. I don't know why you said the AT200 does not interface to the 857.

Subject: Re: [LDG-auto-tuners] Re: Yaesu FT-857D and LDG AT-200pro

Yaesu will not transmit a signal in cw mode when keying the mic. You have to have a cw key.

Also, the AT-200 does not interface with the 857; LDG makes a tuner for that rig.

It will auto tune if you set the menu for 10 watts AM. Turn to AM to tune, then go to SSB.

Brian thanks for the tip about tuning

I have used the tuner in the fashion you mention while transmitting in AM mode,

the FT-857D PTT does not transmit in CW mode only AM and maybe other modes as well.

The Y-ACC cable is supose to place the radio in CW mode and tune, which it does seem to tune
but always ends up in BYPASS mode and then it won't pass any form of transmitting mode.

My old FT 757GXII will transmit in cw by using the PTT it also has a transmit button and works well
with the LDG tuner.

I have not tried my Z-100 yet I will try sunday to see if it works, I would like one button tune.

I haven't seen much discussion of the RT-600 on this site. I would be interested in peoples' observations and experiences. There was some talk recently that the relays are non-latching; it was never clear to my whether this is accurate or not. There have been several (but not a lot) of reviews on eHam, but I always take these with a huge grain of salt!

More generally, I am interested in reliability and consistent performance. I would use the RT-600 at the base of a 43-ft. vertical. Current "street" prices for the RT-600 are around $400.

Another interesting tuner is the Stockcorner JC-4 from the Netherlands. The website pictures show this tuner to be built like a precision instrument. At current exchange rates the price in excess of $600 plus international shipping. My first choice is always to deal with a company based in the U.S. in case there are any warranty or service issues.

Anyway, your observations would be greatly appreciated.

Well, I use the AT-600ProII with a balun for my 102' doublet, and for a 20 meter dipole, and for tuning my Eagle One with 20 feet of coax. It works well. I seem to have good signals on most bands; in fact, I used the 20 meter dipole on 17 once to make a DX contact, and was pleasantly surprised.

As for latching relays, http://www.ldgelectronics.com/c/252/products/20/73/2 says they are high powered non-latching. *HOWEVER*, you are feeding the thing with DC over the coax, right? It should be powered all the time, so all it takes if you have a memory set, as in you have tuned to that frequency before, is to simply transmit, and it will go "clunk" and you are set. Memory tune time is .1 second, so just key the rig, and go.

Latching relays sound good, but are for use when you are on a frequency, turn everything off, and go back to the rig, turn to the same frequency, and start again. If you change frequency, a latching relay can be a problem.

I suspect my AT-600 is about the same thing in a different box. If powered on, it tunes in about a tenth of a second if it has a memory, and about 4 or 5 if not. If it has no power (or is turned off), it is bypassed. The RT-600 is likely about the same thing. The manual can be found at http://www.ldgelectronics.com/assets/manuals/RT600Manual.pdf

Hello Dwayne.

Sorry about not signing my post, most forums I frequent automatically does that for me so please forgive.

Now, I think I have found the root of my problem with my Z11 Pro 2 retuning all the time. I have been using it with my Icom 706 Mk2 with the interface cable so that the radio controls the tuner. The problem is that I had the radio set to PTT tune for use with the Icom AH-4 so that it woul activate the tuner when I keyed the mic. That doesn't work well with the LDG tuner as it gets confused when it gets a tune command every time you key the mic of key the paddle in CW. Anyway, if you guys are using the LDG tuners with an Icom rig, disable the PTT tune so you don't confuse the radio. Right now I have the interface cable disconnected right now but did disable PTT tune and will try that with the cable installed this evening in hopes that cures the problem'

73 - kc8aon

Hello,

Your unit should be sent back for service. Once tuned, it should retune in well less than a second.

Also follow the group protocols, sign with your name and/or callsign.

Why would you want to tune every time you key the mic? Once tuned it should stay tuned, Unless you change frequencies every time you key the mic. <snip>

The way the Icom AH-4 tuner is setup it looks for a match when you first key up and if needed it activates the tuner to provide a match. You just key up and go, but with the LDG tuner it takes off tuning every time if you have it set that way. With the Icom tuner it only tunes on key up if needed and works flawless and is very handy when changing bands or frequency as all you need to do is key the mike or paddle. The LDG tuner just gets confused and tries to tune every time. So now I have it set so that the only time it tunes is when I push the tune button on the radio or the tune button on the tuner. With the Icom tuner and PTT tune all I have to do when changing bands is to key up and start talking and it memory tuner fully automatically in a blink of an eye and I have just grown to expect it to work that way - never even gave it a thought with the LDG until I used the LDG with another radio that doesn't use the interface cable and had to provide some RF to activate it and that's when I noticed that it stayed tuned after the first time and tried it with the Icome radio and viola, it worked !

z11pro in auto mode will tune with first RF. Set it to auto and start talking. Sice it is not tied into the band switching of the radio it has know way to know you changed bands until you actually provide RF. This is the difference between a universal and a propritary tuner.

Oh but it is tied to the radio through the interface cable but I think all it does is to switch the radio automatically to cw mode and reduce power to 10 watts - I don't think the tuner gets any band info from the radio through the cable.

Correct the cable only allows the tuner to kick the radio into tune. It is the exact same function when the tuner is used on Icom, Yaesu or Kenwood. Just the cable changes to mate up with the different radios.

It also doesn't do anything to set the radio to 10W. That is up to the radio. It actually relies on the fold back circuit in the radio to protect the radio.

Actually the Icom radio doesn't use the fold back circuit when in tune mode, it actuals changes to cw and drops the power back to 10 watts which I like real well. Also, with the Icom AH-4 tuner there is a resistive bridge that gives a proper load to the radio when tuning and bypasses the bridge after tuning. But I am very glad my LDG tuner is working properly and last night I did some further checking and it does work with the control cable connected. I can activate the LDG with the tuner button on the radio or the tune button on the tuner either one and it snaps into action. Memory tune is very quick just like the Icom tuner !

Thanks Dwayne,

I'm glad its working too, just never even gave a thought to the PTT tune function on the radio cause it worked so flawless with the Icom AH-4 tuner. It only confused the Z11 Pro 2. With the PTT function turned off, the LDG just requires one extra step over the Icom tuner and that's just a button push.

If you look inside the unun, the shield of the coax is connected to the ground terminal which makes it sort of a counterpoise. If you have problems with RF getting back into the radio using it that way, you can install a choke near the radio to eliminate or remove the RF.

Date: 2015-10-21 10:25:17 UTC
From: k4pdm@...
Topic: 7530 Message: 7530

I recently purchased an MFJ 989D "legal limit" tuner. It works fine, but I am wondering how the LDG ProII would work for me.

I do run an amplifier but never over 1000 watts, usually 600 or so.

My SWR is not extremely high. I think the LDG would be able to match it with no problem,and I have an external balun already.

My question is, how close to 1:1 does the LDG get on its own? The manual MFJ lets me dial it down exactly and I like that. Will the LDG do that or will it come no closer that 1.5:1 or thereabouts?

I understand there is no practical difference. I just like to see the reflected meter at 0.

Thanks & 73 Paul K4PDM

A little experiment I did a few years back when I was playing with portable antennas was to use ferrite beads on the coax that were not taped in place. I would stretch the coax out on the ground and slide the ferrite beads to the quarter wave point for the band I was operating to somewhat tune the coax shield to resonance. I was using 50 feet of RG8X and best match was usually obtained when the ferrite beads was placed a couple of feet short of the full quarter wave length - around the 30' mark for 40 meters as I recall and the shorter than normal length was probably due to the coax laying on the ground - worked fairly well as a tuneable counterpoise !

Good morning, Paul.

I don't have the Pro-II model but I have two AT-1000Pro and three AT-1000. I run them all at from 500 to 900 watts, on a wide range of frequencies including several MARS and CAP frequencies that aren't harmonically related and are some distance away from any ham band.

Antennas include an inverted V cut for about 1.7 MHz and fed with ladder line; another inverted V cut for about 2.5 MHz (that's all the room I had for that one) also fed with ladder line, an off-center fed dipole for 80 and 40 fed with RG-8 coax thru a 4:1 current balun, and an end-fed Zepp for 40.

The LDG autotuners work just fine with all of them. You may not always get down to an absolute flat 1:1 automatically (often you will, occasionally you won't), but if, say, 1.4:1 isn't good enough, the autotuners all have Cup/Cdn and Lup/Ldn keys you can use to manually tweak the settings.

I haven't touched a manual tuner in many years, and have always had good luck and good service with these LDG tuners.

VHF Sensor for DWM-4 Wattmeter For Sale:

I have a VHF sensor for the DWM-4 available. It works 100% and looks fine as well. It includes the sensor, the cable (fairly long), and paper work for $75 plus shipping from Florida. It was calibrated by LDG a year or so ago.

I also have many other accessories available such as many different types of microphones, HTs, VHF and UHF rigs, antennas, etc. Just too many things to list here. Please e-mail your requests.

Thanks.

Hi, Paul ,

I have had an MFJ 989D to get my " match " downas well,and have run legal limit output into a fanned dipole on 80 to 0

meters .

Three years ago , I purchased an LDG AT1000 PRO 2 , and changed from a fanned dipole to an OCF 80-6 meter
dipole ...and also reduced out power to Ameritrol AL 811A " WHEN NEEDED " , and that was the best purchase

I made in my 35 plus years of being a " Ham " .

The first thing you want to do if you get one ,is read and understand the manual ,and follow the instructions ,

Duane an his crew make very good products , and stand behind them .

It took me a little time to get used to the clicking sounds of the tuner to find a " match " , but now when I

change bands , it just takes a tenth of a second to remember for the tuner to tune . Remember that all the tuners

do is lie to your transmitter !

The best match is in the antenna itself , the tuner does not change the physical length of the antenna ,and

the modern tracievers are useible with 2 to 1 match . While you are being a " nit picker " and getting as little reflected

movement from the needle, you might be missing a contact with a rare station on the air ,and causing QRM on the bands

where ever you " tune " the antenna . The LDG AT1000pro 2 has worked without a problem for me !

Have fun in the hobby ,and happy DX,

Art

Subject:[LDG-auto-tuners] LDG AT-1000ProII vs. Manual Tuner

I recently purchased an MFJ 989D "legal limit" tuner. It works fine, but I am wondering how the LDG ProII would work for me.

I do run an amplifier but never over 1000 watts, usually 600 or so.

My SWR is not extremely high. I think the LDG would be able to match it with no problem,and I have an external balun already.

My question is, how close to 1:1 does the LDG get on its own? The manual MFJ lets me dial it down exactly and I like that. Will the LDG do that or will it come no closer that 1.5:1 or thereabouts?

I understand there is no practical difference. I just like to see the reflected meter at 0.

Thanks & 73 Paul K4PDM

7536. LDG z-100 Plus buzzing or ticking sound

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-10-28 12:37:30 UTC
From: vk2jdr@...
Topic: 7536 Message: 7536

I recently purchased a new Z-100 Plus and found it makes a buzzing or ticking sound in time with CW sending.

If the tuner has no power connected, it makes a buzzing sound which increases in frequency as the power is increased. If the power is connected, then it makes a tick sound on each key down.

I have taken it back to the shop to be looked at however the technical report came back saying it is RF feedback and some noise is normal. I will be loaning another unit shortly to confirm if this is true or not.

I do not agree with this as it makes the sound connected to either of two different rigs (FT-920, FT-857D), with a dummy load connected and running on 12v battery.

The ticking/buzzing is loud enough to be heard several feet away and is to the point now where I will not use it as the noise is off-putting when sending CW.

Has anyone had a similar problem or know why / how to fix this ?

Regards,

David VK2JDR

Good morning, David.

I can't say for sure, but I have several LDG tuners from 100 to 1000 watts rating and I have never heard that effect on any of mine.

The LDG tuners are, perhaps more than they should be, subject to RF interference. For example, my two AT-1000Pro tuners will occasionally freeze up when I transmit at high power, requiring a power cycle to get them back. I have cut down on this, though not eliminated it completely, by adding clamp-on ferrite chokes to the 12 VDC power in. Just adding a small choke to the line won't do it... you should get one of the proper material (mix 31, 75, or 77 should work) that's sized for RG8X or larger, and wind several turns of power cord through it.

Hello Rick, thanks for the feedback (no pun intended!) It makes the noise even if there is no power connected and I have been using internal batteries to power the unit. It happens on all bands and starts making the noise from about 10 watts and up.

I'm using a LDG RT/RC-100 at the base of a G5RV 102ft antenna, running back to my Yaesu FT-897D with a LDG FTL-Meter set to SWR on Tx. As the atu tunes, the meter dips below SWR=3 several times, but then comes to rest at SWR > 5. I see HSWR on my rig's meter as well, in agreement.

Why would the atu not select the lower SWR?

Topic: 7540 Message: 7540

I notice when my Z11 Pro2 is tuning that the swr dips to almost nothing several times during the process, but will tune past that point several times and settle on a higher swr or quit tuning like it can't find a match at all. Why is that so ? I would think that the first time it dipped to almost no swr at all it should stop at that point. Watching it on a known good meter between the tuner and the radio and the swr indicator on the radio both verify that it is finding a very good match but then settles on something higher. Just doesn't make sense to me at all ?

Actually mine doesn't tune to a higher swr (not always anyway) but it does find a good match and keeps on tuning so long that the tune feature on my Icom 706 Mk2 times out before it locks in which forces me to switch to AM or CW and key down so it will finish the cycle. When I do that though, it starts all over again. This is of course on a new frequency or antenna that has not been stored in memory yet. I'm just wondering why it keeps on tuning when it has dipped past a 1:1 swr several times in the cycle ? You would thing it would just stop and lock it down on the first one.

My z11 pro2 doesn't do exactly what you're describing but if I tune it then put it into bypass and then reactivate it, it usually will totally lose where I had it tuned to and will need to retune it all over again. Sometimes I have to do a full tune to get it back to where it was even though I had the tune stored in the memory already. If it is a difficult tune, sometimes I have to tune it twice to narrow the swr as low as it will go for that given frequency. Not sure if all of this is normal but I don't remember having to do all this when the unit was new. Not exactly what you're experiencing but maybe along the same lines?

I had a similar problem with a new AT1000 Pro II and sent it in for repair only to have it returned stating nothing was wrong with it. I have a second, but older AT1000 Pro and it would work fine. I couldn't get the folks at LDG to fix it so since it was new I returned it to the company I purchased it as a defective unit. I love these tuners when they work well but can't say much about their factory service. The reason I returned mine was it was kicking out high SWR's and I didn't catch it in time so I burned out my power transistors in my rig. Be careful.....

Yeah, mine has done that since it was new too. Sometimes it just refuses to store settings in memory until I make it tune a couple of times. Then whenever I shut down and return the next day thinking settings would be stored after using it the previous day, it starts the sequence over again. I don't think its anything going on with the antenna either as I can tune it with a manual tuner and it stays tuned from day to day unless I change frequencies or bands. But the LDG sometimes just doesn't store the settings even when using the store button and the next time I use that antenna/frequency, its a toss up as to whether or not it will tune from memory or a new tunig cycle - sometimes yes, somethims no.

With my AT-100ProII and AT-600ProII, it looks, on a SWR meter and on the face of the unit as though it has gone past a low SWR several times before it seems to pick a "higher" one. If you start fiddling with the "C" and "L" buttons, however, you will find that it indeed has not.
Occasionally, I can tune the L and C buttons, and get a slightly lower one, but it usually is not worth bothering with, it is just a response to my OCD.

I'm also experiencing similar issues. I get buzzing even if I disconnect the tuner power and control cables. I plan to place a common-mode choke close to the tuner (already have one near the antenna feed-point, model ZRW-B11-ISO.) I'm hoping that the choke will fix it once and for all.

If anyone has any *toroid* recommendations for something that will work for hf that can accommodate two or three loops (preferably more) of RG-213 that would be great as I'm hesitant to blow another $40 or so for another choke balun.

Come to think of it I believe mine has done that sort of thing before also. Or something close anyway. It hasn't done that in a while so it's weird that it was going on at all before. It's like something was broken inside then it miraculously stopped being broken one day. So strange. I did redo the jumper going from the tuner to the plug running outside to the antenna. May have been a bad connection there causing it to detune randomly, especially when the wind blew.

I've been making up a crate that I used to go "portable" with back 25 years ago.
I have a new Yaesu FT-857 that replaced my old FT-757GXII the rig is nice and small works all bands but is a bear trying to learn all those many features.
I bought a Z-100 to use with my Ten-Tec QRP rig since it has a built in battery pack as does the Ten-Tec they work great together. when making up my new old crate I found I had lots more room than before. I mounted the Yaesu and a power supply on the lower shelf an SWR/POWER meter the Z-100 and a SignaLink USB on the upper shelf. which leaves room under the lower shelf for either paperwork or a plywood slide out shelf to use as a desk or a set of paddles.
I just love the way the Z-100 works it will tune my Packtenna antennas or my Hustler whips I don't
run mobile I just set up the whips when I can't set up the Packtenna.
I also have a 200 Pro 2 here in my home shack it works great as well.
I don't have any reason to tell you all this just that I was sitting here thinking how great the
LDG tuners work and thought I would share my thoughts.

My AT-100 PRO has done this for the past 8 years that I have owned it.

The SWR algorithm in the computer is off calibration, I suspect, or is corrupted. I tried at one time to get a new "eprom chip" from LDG for the firmware, but they never came through and said it was not available....

In the past, to get around this, I would just use the L / C buttons to hunt around for a 1:1 match, which was typically far away from the match that the tuner had "computed". Once i found a match, I would force a memory save (F+Tune) for a low SWR a memory positions. This worked but so much for "autotuner"....

Doing an actual algo-based antenna tune, it would almost never find a "good" match (less than 1.5:1 despite the "threshold" being set to 1:1). What's worse, it still tends to want to occasionally go into a tune cycle randomly, as if RF is getting into it, unless it is set to "fully manual" mode (F+Cnd).

I should mention that I use well built and very stable dipole/resonant antennas and use them only for the band they were designed to operate on. The resonant frequency of the antenna does NOT move ever....

40M is particularly flakey for this tuner. It's pretty frustrating so I eventually relegated this tuner as an expensive A/B antenna switch and LED SWR/Power meter..... Sorry, but as a tuner, it's pretty much junk....

The MFJ manual tuner works better and with a slip of paper I can retune in a matter of seconds and always have a 1:1 match, and always is a perfect match when returning to the settings on my slip of paper.

maybe the algo has been improved since my tuner was built. Mine is firmware version 1.0

I have an LDG100 pro ... It's about 9 or 10 years old. It has always done things like this.

Most frustrating, it does not find a 1:1 match despite the antenna being resonant. I can use the L/C buttons and find a perfect 1:1 match and then store into memory but those are often lost within a day or two. I use the SWR analyzer and find a perfect match and write down the L and C settings.... I can usually dial those back in ... but this thing is supposed to be AUTOMATIC !

My antennas are resonant dipoles - 40 meters seems most frustrating...

I have firmware 1.0 years ago i tried to get a new eeprom from LDG to upgrade the firmware but they did not have those in stock.

Now i use this as a fancy A/B antenna switch and LED swr/power meter. As a tuner, it's just frustrating to not work properly as an automatic tuner.

Been a ham for 30 years.... I can say that on the same exact antenna, the small manual tuner from MFJ works to find a 1:1 match every time, the manual antenna tuner never needs to be re-adjusted unless changing frequencies and always holds its settings! My dipole antenna has been up for years and NEVER changes it's resonant points.

A resonant antenna doesn't mean a 1:1 SWR, and a resonant antenna is only such on one frequency, or a very narrow band of frequencies.

Have you ever measured a difference in signals, or other operating parameters between having a 1:1 SWR vs. a ~1.5:1 SWR?

You didn't say what results you get with the auto tuner? What usually is the SWR when it's done tuning?

On mine, it will dip to a 1:1 several times and then settle for something like a 1.7:1 or even a 2:1. To be fair it doesn't do it all the time and sometimes I can keep forcing it to tune again and finally sometimes it will stop and store a better match, maybe a 1.5:1 or better. Its just frustrating to watch it pass up a 1:1 several times and settle for something higher.

Sure on providing input.

The readable SWR changes as the tuner goes through it's tuning cycle. There will be periods (in milliseconds of time) where the tuner has selected a bad match. During those times, the radio may drastically reduce the RF power. If the RF power is dropped at a certain rate, the tuner does not use those readings.

So the SWR may show a minimal amount when there is no RF. This is because RF is required to calculate the SWR. In those instances, that are very minor, the SWR is non-calculable. The radio and tuner may or may not show low SWR readings while there is low RF power.

The radio may show low SWR, but it's more likely that there is not enough RF power rather than the tuner has found a good match and tried to proceed past it.

Also remember that the radio has a different RF sensor than the tuner. There may be times that they don't agree.

I hope this helps,

Dwayne Kincaid

Well, I hear what you are saying but I'm not depending on the swr circuit in the radio but on a dual needle meter that is between the radio and the tuner and when the swr meter dips to 1:1 and the radio is doing full output as shown on the forward meter and the tuner passes this up and settles on a higher swr is the part I don't understand. The tuner specs, correct me if I'm wrong says it needs a minimum of 0.1 watt to tune and the radio is doing about 10 watts out in the tune mode when the meter displays a 1:1 swr but passes right on by and settles on something higher. Granted it does most of the time settle on something useable like 1.7:1 or 2:1, but why not have it programmed to settle on the lower swr ? This would make tuning quicker and put less stress on the transmitter. I have both the Icom AH-4 and the SGC-237 tuners and they both lock on as soon as they hit a good swr, I just don't understand why the LDG doesn't do the same. Yeah, I know that's comparing apples to oranges.

When tuning, the tuner never "settles" on an SWR reading. It always tries to find the best match that it can. It does not stop at 1.5 (not sure where you heard this).

Again, an external meter may drop to a good SWR, but that does not mean the tuner (or the radio) saw the same thing.

Unfortunately, the SWR reading is "always" for the radio's benefit. The current definition of a tuner is that it makes a crappy antenna load seem good to the radio so it will put out full power. It's better to have full power to a bad antenna than to have the radio limit the power because the antenna is bad. So we always use the SWR meter on the radio as a gauge of what is being transmitted.

It sort of sounds line your antenna may be on the edge of the tuning range for the tuner. The other tuners mentioned have a much wider tuning range, but mainly only for long wire type antennas. Those type antennas typically have very high impedance.

I agree with Dwayne. Mine almost always picks the best match. Sometimes it looks like it picked a lower SWR, but if I watch the output on my transmitter, it fluctuates. It may be off slightly on its own meter by a tenth of a point (say from 1.5 to 1.3), but I see this as negligible.

Well, the antenna I use it on is my off center fed dipole and mainly only use the tuner on 75/80 meters where the swr without the tuner is araound 1.7:1 @ 3.5 MHz and around 4:1 @ 4 mhz. really not all that high and well within the range of the tuner going by its specs. The antenna shows no resonance at all on 30 and 60 meters, bout bands are around 5:1 swr but the tuner seems to work well on those bands, its just on the portions of the 80 meter band that it acts quirky. The antenna is great on 40, 20, 17, 12, 10, and 6 meters without the tuner.

Randy not knowing what radio or tuner you have it's hard to tell. On my old Yaesu 757 it had a MOX button that could be used to tune.
on my new Yaesu 857D I would put the radio into AM or DIGITAL mode
and key the PTT, seems the FT-857 wont transmit in CW using the PTT.
Now I have two tuners a 200 proII and a Z-100 I bought a cable ACC-Y that
goes from the radio to the tuners now all I have to do is push the TUNE button
on the tuner and it keys the radio and lowers the power out.
Hope this helps.

Most radios have a Tune function that puts out a CW carrier at reduced power, The setting is adjustable also on many rigs. I have a K3, FLEX-1500 and Ten-Tec Argonaut VI all have an adjustable Tune mode. That way you aren’t running fully power into a miss-matched antenna. Many current radios don’t have an AM mode but all have CW. Using SSB there is no carrier to provide output until you modulate it with a tone or voice.

I use the LDG 200AT Pro with my FT-950. I put the radio in CW mode and hit my key. It tunes it up and the power automatically drops down to 20 W’s. When I first got it I went thru the frequencies and tuned it up every 20 Kc’s so now it pretty much knows. Of course now you can get the YT-1200 for it and it connects to the 232 port and when you start to talk it just tunes it automatically.

They will work with any radio, just not "push button" on all. Mine is s FT-950, and they make no interface for it. I just push the "AM" button, transmit, then go back to SSB. It works just fine.

OOPs what radio are you using also. I should have asked that also. Several of the LDG tuners are set to work with the FT-857 and 897 so when you push the tune button it put the radio in AM and tunes and when its finished tuning it puts it back in the mode you were in. I wonder if they have other tuners that work with other radio brands.

Subject: [LDG-auto-tuners] WHAT MODE TO TUNE

What mode should I be in to tune?
If I use SSB, I hear the relays click several times, then the Tuning LED blinks 5 times.
Do I need to transmit some kind of tone?

i just picked up a at-1000 pro from a estate sale and seems to work ok, but the meter seems to bounce around when i have radio in cw mode before tuning, it goes from like 70-80 then 100 watts back and forth it goes so does the reflected needle a little bit. it jumps fast back and forth the needle acts crazy. also does this on a dummy load too. hope that makes some sense !!!

anyone know what the issue is or can i get a replacement meter or what ??

thanks 73

I think that is not unheard of or abnormal with auto tuners, which step through various combinations of L and C on the way to an acceptable match. I've not read the manual, etc. but I would avoid tuning at that power. Switching under power can over stress components, result in arcing and other bad things. I have an AT4 and a RT100, both of which are limited to 100 or so watts anyway, and both prescribe tuning at 5-10 watts. All the manual tuners I am familiar with suggest similar precautions.

Power fluctuates according to the load. If the transmitter sees a bad load, as it well can during tuning, it shuts back power, for one thing.

Use low power to tune. Everything else sounds "normal."

W6OGC>> I would avoid tuning at that power

The AT-1000Pro doesn't allow tuning at higher than the maximum rated tune power anyway. It will flash its LEDs in a sort of checkerboard pattern, warning you that the power is too high to safely tune.

The AT-1000Pro is rated to tune safely at any power from 5 to 125 watts, so it seems like Barry's tune power is about right.

Barry, do the needles jump around like that WHILE tuning, or before or after tuning? Jumping around while tuning is normal, before tuning might be an artifact of your radio reacting to a high SWR (what radio?). If it does that after tuning, you may have an antenna or feedline problem... but you say it does that into a dummy load too... any chance of a loose connection in the coax from the tuner to the dummy load?

I have two AT=1000Pro tuners and three of the older AT-1000 (non-Pro), and haven't seen a failure mode like that in the tuner itself, hence thinking, if it does this after the tune cycle completes, that it might be something else in your setup.

When I key the radio before any tuning of tuner before or after so basically just keying radio it's just bouncing fast around. Like it goes from 70 to 100 watts and also the reflected needle does the same movement. Other then that tuner seems to work fine, just the bouncing off needless is driving me nuts..

Barry;

Do you have another radio to try, or can you get with a ham friend and try it on his? Does it happen on all bands or just on one? (You can verify that with the dummy load.)

If you have a separate wattmeter or even just a separate SWR meter, try putting that in the line between radio and tuner, then between tuner and load, and see if its meter jumps around in sync with the meter in the tuner. That would help isolate any issues between the metering circuit and the tuner circuit.

Just kind of grasping at straws here, but it doesn't sound like a failure mode of the tuner except for perhaps a loose connection in the metering circuit, or marginal relay, and it would be good to be able to absolutely rule out everything else except the tuner.

Alex,

That is not correct. If it's not a tube radio, there is no danger of damage to the tuner or radio tuning at 100 watts.

Also the relay are not rated at 100 watts, they are rated at just over 1000 watts. Please stop posting incorrect info or guesses.

The tuner also has safety software built in that will not allow the tuner to tune if the RF power is over about 150 watts.

OK - silly question. On the FTL-Meter PWR scale, what's the first tick before the tick labeled 10? This page has a pic that's pretty clear LDG FTL-METER: Ham & Amateur Radios - Equipment, Parts and Supply | AES
http://www.aesham.com/analyzers/swr-meters/ldg-ftl-meter/

When I set to 5W on my FT-897D, the front panel scale shows 5W, a MFJ-828 Digital SWR/Wattmeter says 4.7W, and the FTL-Meter needle is exactly halfway between the two ticks. As I ramp power on the FT-897D, it seems dead-on at 10W, 20W.

I can't answer your specific question but it has always been the rule that when using analog meters the greatest accuracy is in the upper part of the scale. Could be a factor here too.

Do you have the specs for the FTL-Meter? I'd suspect that such a meter would have 10% accuracy, as would the one on the FT-897.

0.3 of a watt at 5 watts would be about 6% difference.

That's my take on the situation, not at all scientific, but, to me 4.7 and 5 seem within tolerance for most amateur radio applications.

7600. YT-1200 Tuner FT-991 blocks keying VHF Amp, Linear, or Xvtr

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-12-02 02:46:32 UTC
From: jimeagle1@...
Topic: 7600 Message: 7600

Looking at the YT-1200 manual it looks like I would need to 'hack' the cable that supplies power and ground to the LDG tuner to also bring out the "TX GND" pin to an additional short cable going to an RCA Jack to use to key other accessories that may be on the "TUN/LIN" jack. In my case this would be a 222.1 MHz transverter and/or an HF, VHF or UHF amplifier.

It would have been nice for use with the FT-991 if a female RCA jack had been made part of the cable supplied to connect the 991's DIN 8 pin Jack to 14VDC Power jack used to power the YT-1200. Alternatively an RCA (or other jack) on the back of the tuner would allow passing the TX keying circuit through to other accessories.

Well I'm just about convinced I have a faulty Z-100 plus autotuner regardless of it being "tested" by the technician at the place of purchase. The feedback was RF feeding back causing the problem, regardless of it being on a dummy load, resonant antenna, battery, etc. I feel I'm just being fobbed off on this issue.

I have since borrowed a YT-100 tuner, plugged it in and not a squeak - as I would expect. This model tuner doesn't seem to be bothered by RF feeding back! Oddly enough it looks very similar to the Z100 plus apart from the CAT interface.

Looks like my Z-100plus tuner will become a very expensive door weight as I can't use it with CW listening to it ticking away in the background.

Does anyone else have an issue similar to mine with it ticking in tune to CW being sent ?

Hi Leonard,

I'm running an FT-857D and also run it on an FT-920. Makes no difference.

If you semi-mode means by-pass, yes I've tried it in by-pass. Also makes no difference.

How are you powering it? There is a possibility that RF could affect a switching type wall wart and causing some radical fluctuations in DC out. Mine is powered by my radio. For a box that is full of RF when it is in operation, it confuses me how a bit of external RF could be an issue. The PA stage of the Collins 821A2 was a tuned cavity and at 250 KW it worked perfectly, that is RF folks!

Hi Steve, it's being powered by AA batteries installed inside as per the LDG youtube guide. With the batteries installed the unit makes a ticking sound (like a relay activating) yet when I pull the battery pack out, the ticking changes to a buzzing sound, with the speed of the buzzing increasing with power. I think I will produce a youtube video so the sound can be heard. It is rather loud, I can hear it with my headphones on.

Regards,

I have the exact same symptoms as David in regards to the ticking changing
to a buzzing sound, depending on whether the unit has power or not.

Well I took it back to the retailer along with my rig and battery and tried another Z100 plus. It is exactly the same i.e same buzzing sound on key down.

I ended up exchanging for a YT-100. Now works as expected and silent when sending!

7610. LDG AT-200Pro (not a pro II) current draw?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-12-16 11:44:46 UTC
From: fudgies@...
Topic: 7610 Message: 7610

Hi All,

Just out of curiosity really, I wonder has anyone else noticed this issue?

My AT-200Pro (not a pro II) draws approx 500ma when powered on. This is even with no RF applied, and also when the radio is powered off. I have discovered that with a single press of the Tune/Store switch a relay switches and the current draw drops to approx 100ma. I can toggle between the higher and lower current consumption with this switch. Pressing this switch the relay is quieter when the current draw is higher, then the relay gives a louder clunk for the lower current.

It is working OK other that this little glitch, the user manual states that the tuner goes into "deep sleep mode" after a few seconds and draws only a few ma but this one doesn't seem to do that and it has always been like this as far as I know.

I preformed a full reset on the tuner which cleared all the memories and reset it to factory default settings but it's still the same. I run it off the same PSU as the radio so maybe it's a ground loop or something, as the Radio (FTdx3000) draws approx 100ma even when its switched off which is normal for this rig.

Any ideas?

The short push of Tune switch puts the tuner in bypass mode so all
relays disengage. In tuned mode relays are engaged so they draw
current. Unlike some of the other LDG tuners the AT200 does NOT use
latching relays so it take current to keep them engaged.

Thanks Leonard, I didn't know that the tune switch put it in bypass mode, you learn something new everyday. It's seems so that the LDG user manual is misleading that there is no such deep sleep mode where the unit draws just a few ma. Do you still own a AT200pro & FT-950 if you do I wonder are you getting similar power consumption readings on yours? It's a fairly similar set-up to mine with the FTdx3000.

Yes I still own it. Would be hard for me to take a power reading as I have mine powered off the 950 using a cable I built a long time ago. My manual has the power consumption rating as:

Power requirements: 11 to 15 volts DC at 500mA (750 mA max during tuning)

What's in your manual makes more sense Leonard so it may have been updated, my manual has this paragraph,

""The relays operate from DC supplied by via the power input jack. The total current drawn by the
AT-200Pro depends primarily on the number of energized relays, with the maximum current drain being approximately 750 mA, but only during the few seconds a tuning cycle is running. At
all other times, the tuner is in a “deep sleep” mode drawing only a few milliamps. The last tuned
setting is automatically reset on the next power-up.""

I'm beginning to hate auto tuners altogether ! While trying to work DX on 17 meters over the weekend, I look up and notice my power output is way down and the swr is sky high. Hit the tune button and the swr drops to almost nothing and 2 words into a call and it does it all over again. power drops and swr skyrockets. So I give up on auto tuners. This is my third LDG product and have had the same problem with every one of them - they just won't stay tuned. I've tried everything I know from putting ferrites on all cables, used chokes everywhere, set the threshold higher, made sure its well grounded etc etc, and nothing I have done will allow it to stay tuned except on a few frequencies. So for now my Z11 Pro2 is going in the closet and I put my old reliable MFJ-949D back in service. Its a lot slower, but I know it will stay tuned no matter what ! By the way, never did work the DX station because of the problem.....

If you're only gonna operate on one band, sure. If you switch bands a lot, it is a chore to tune the tuner every time. If I have ever operated at a frequency, the tuner says "click", and it is there, no need to run a tune cycle.

Hmmmmm. I use a LDG AT-600Pro II Autotuner for the station, and a AT-100ProII for my mobile/portable/Field Day. Both work like champs. I have worked almost every DX I have heard, and I use a SB-200 when I have trouble.
I have had troubles like you describe, and it was a bad connection somewhere.

I use a 4:1 voltage balun (from a Heathkit SA-2040) for my antenna, which is a 102' doublet fed with balanced line all the way back to the shack.

After using manual tuners, and missing DX while tunng, I cannot see ever going back.

Thankfully my LDG 100 PRO has not given me that problem. However like you I have my MFJ 941B and 944 permanently hooked to two additional antennas which I can select quickly as needed.

Never can have too many antennas--right!

7625. AT-600Pro AutoTuner to FT-dx1200 adapter cable

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2015-12-21 19:20:04 UTC
From: ad7gr@...
Topic: 7625 Message: 7625

My AT-600Pro AutoTuner to FT-dx1200 adapter cable project.
I used a shielded stereo audio cable from my "junk box", wired the Linear plug's TX REQ IN (pin 10) to the (1/8") plug's tip and it's sleeve to GND (pin-3)... no connection to the ring... just as Chris, VK2BYI, described in his article (http://www.vk2byi.com.au/at-1000proii-memory-tuning-issue/ http://www.vk2byi.com.au/at-1000proii-memory-tuning-issue/). I set the AT-600Pro automatic tuning mode to Auto, my 1200's Menu #179 Tuner Select to External.

When tuning is initiated by a medium press of the AT-600Pro's [Tune] button, the 1200 reduces TX power, goes to TX until a match is found and then drops out, returning the 1200 to it's previous power setting... just as it should. It's great to have this additional ease in tuning.

The Linear plug is a 10-pin mini-DIN plug which is available on the Internet. Understand what you are attempting before beginning this project. Chris has a nice image of the Linear jack. (BTW... Do NOT use the 1200's [TUNE] button).

After using manual tuners, and missing DX while tunng, I cannot see ever going back. <snip>

That's why I switched to an auto tuner in the first place. I don't get a lot of time to operate and would love to spend less time tuning and more time calling. The thing that bothers me is that the antenna isn't that bad on 17 meters to begin with - about a 2.5:1 and it tunes real quick with the Z11 Pro2 on that band, but then start calling and it starts trying to retune and the swr shoots way up which makes the rig fold back dropping the power. I have 2 other auto tuners, the Icom AH-4 and the SGC-237 but they are mainly designed for end fed wires and whips and not coax fed antennas. I have used them with coax fed antennas, but they really don't recommend it.

Try pressing the key combo that locks the tuner. Forget what it is, but I have to do that on my 600 Pro II sometimes.

Good point.

I was thinking of something like that being wrong. Under low power tuning it might work just fine. When you start to transmit, the higher power breaks down the connection momentarily. I've seen many PL-259 with the shield not soldered. A little corrosion and you can have a problem like this.

I have 10 LDG tuners including three AT-1000, two AT-1000Pro, and five smaller tuners, and all have performed flawlessly in every environment from the shack to field portable to mobile, never a problem after I added chokes to all of the power leads to the tuners.

My guess would be a loose connection somewhere in your rig-to-antenna path, or suboptimal grounding, or just lots of RF in the shack.

I have several of the LDG tuners. And like them, have no problems with them and use them. But I have to confess that over time I've drifted back to my Palstar AT2K tuner for more than half my operating. I don't preach this as the gospel or as a better way. I think it may have more to do with me being a 13-year-old kid trapped in the body of an old bald guy. I enjoy the process of tuning, of turning the knobs on my AT2K. It makes me feel like a ham. Again, this isn't advice or argument, but after reading all this I just felt to let you know.

If ham radio was a business and I had to be efficient, if every second counted, I'd probably stay away from my manual tuner. But since it gives me pleasure I won't worry. I do have several of the LDG tuners and think they are top notch and do have them connected to some of my transceivers. But on my main radio and amp, the AT2K sits there waiting for me to do some tuning - to get things down to the point where the SWR needle doesn't dare to move, even a bit and stays right there. If I miss some rare DX, I think - after 50 or so years in the hobby - I'll get over it.

I had a coax connector on a Rat Shack RG-58U jumper go bad on me during
the recent RAC contest. Took me over 30 minutes to figure it out, since
this was the first time in my 60+ years of hamming that this happened to me.

BTW, my LDG Z-100 (original model) has worked like a champ for 5 or more
years. It was sold to me for a song because the original owner put it
in the rear ledge of his pickup and the lid of the plastic case warped
so I need to either replace it, or do what I've been doing for 5 or more
years - use electrical tape to hold it together. :)

Just about every antenna anomaly I have ever experienced in 56 years was traceable to a bad connector, bad soldering of coax to connector or bad coax. If I build an antenna, either from store bought which I avoid, or home brew per an article, and it doesn't tune up, take power as anticipated, that is the first thing I start looking for.

The one exception I can recall was a giant quad I built very carefully from a QST article. When we got it on the tower it was lousy, no F/B, SWRs all over the place, almost deaf it seemed. After a good deal of head scratching, wailing, and consultation with the article author, we figured out I had used insulated solid No. 12 instead of enameled wire. Something about velocity factor. I spend more than a week of evenings scraping the insulation off the ~1000' of wire, with the antenna sitting on the tower just above the roof, me on the roof with a pocket knife. Once I got that back up, the antenna performed spectacularly.

It's always something!

I've checked all my jumpers and the solder connections are all solid. Even made up new ones and replaced them and it does the same thing. When I make a jumper, I first solder the shield to the reducer then once its screwed into place I also solder that to the shell. But at any rate its not a connection problem. I even checked for RF problems with no detectable feedback on the shield and the coax feeding the antenna has 12 #43 ferrite beads on it where it connects to the tuner. Folks keep saying its an RF problem, well for one thing, I thought a tuner was designed to handle RF ? Just doesn't make sense to me, but at any rate the LDG will be relegated to use portable with QRP rigs where the low power should eliminate most of the "RF" getting into the tuner because every one of them I've had didn't like it when I dumped 100 watts into them and acted weird in some way or another. And its not like I'm trying to cure a huge mismatch because the antenna is an off center fed dipole that is very close to resonance in the first place and only needs the tuner in small portions of some bands. The highest mismatch it has seen is about a 3:1 on the upper end of 80 meters, and by the way it has done a fair job down there. OH well, nuff said.....

Good morning, Richard.

I understand the frustration but it would be a real shame to give up on the convenience of the autotuner just because of this, when so many of us have had excellent success with them at power levels all the way up to 1000 watts.

For one thing, 12 #43 beads is often marginal at best; depending on how much RF you are trying to suppress you could possibly need as many as 20-25 of them (really!!) to truly suppress the RF on the coax.

For another thing, the tuner end of the coax is the wrong place to put the beads; they should be at the antenna feedpoint end. If you're going to do that, though, you're far better off with a 1:1 choke-type (current) balun or unun. I use 20 beads on my extended double zepp feedline only because I had them and did not have a spare 1:1 current balun, and they work pretty well (which is to say, well enough) although the choke balun would have been better and I will probably change it in the spring.

Make sure the ground stud on the autotuner is grounded with a fat lead as short as practical; don't depend on the shield of the coax jumper to the rig to provide the ground.

Finally, the power cable to the tuner should be looped several times through one of those #43 beads you have. I did have issues with my autotuners at higher power (500+ watts) until I did that.

Before you completely give up I would add 10-20 feet of coax or more to the antenna line and see what happens. I've seen this fix some problems where the antenna is not quite resonant and the antenna tuner is trying to fix some odd L/C combinations. It's worth a try and easy to do.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } I'm glad I didn't buy an auto tuner, then.
My current setup, with manual tuner, has no problem with RF even at 1kW into ladder line that runs all the way to the desk. I have no chokes or toroids whatsoever.

I understand these problems are solvable but I'd rather not have to go thru all that when what I have simply works.

Hello to the group;

I was given a LDG FT-Meter however it did not come with the cable that connects it to the radio. I checked on cheapham.com and they want $40.00 to ship one to Canada.

Is this a "special" cable that you need to purchase, or can one be made?

I'm new to this group and did a quick search but did not find anything. Please accept my apologies if this has been answered before.

No firmware or software changes needed Brian. However, in addition to my previous post set the 1200's Menu #179 Tuner Select to External. I'd missed that step in my post... sorry. Pressing the [Send] button on the 600Pro initiates the FT-dx1200's tuning process and rig does the rest.

--
73,

How did you 'program' the tuner to talk to your Yaesu so the the power was reduced, etc? Doesn't there have to be some firmware or software changes?

I am not so sure. I have an FT-950 here and have found no cable. Oddly, I have a IC-7000 that has a cable that will work on any tuner. I also got a tuner cable from MFJ for the 950 that allows the use of the MFJ tuner (a 993B) with the 950. I wonder if the same tuner interface would work for LDG tuners. Ii is the MFJ-5124Y. I have thought about trying it, but it hooks to the "TUNER" port on the back of the rig, and that port is used by the linear amp interface.

I use an LG AT-600Pro II autotuner. No chokes, no toroids, no beads except for one on the power cable, no problems whatever. I could only afford 600 watts (a SB-200), and ran a Heathkit SA-2040 with a 4:1 balun. I got so frustrated with having to crank the big roller inductor, tweak the caps, and if I changed frequencies, do it again.
I run a 102 foot center fed ladder line feed antenna with ladder line all the way back to the shack, and a 4:1 balun (from a Heath SA-2060) right next to the tuner. The 200 pins the meter on the tuner on all bands except 10 (abt 500 watts), and I never have any problems. I have a setup that is RF Central; I am on the second floor with a ground that is about 10 feet of #12 wire to a rod, and another wire to the cold water pipe (copper, and well grounded).

I can understand people wanting to stay with a manual tuner (I guess...), but I certainly like my autotuners (3 of them), and my manual tuners have been stored away or sold.

Don't knock it til you've tried it.

Good morning, Richard.

I understand the frustration but it would be a real shame to give up on the convenience of the autotuner just because of this, when so many of us have had excellent success with them at power levels all the way up to 1000 watts.

For one thing, 12 #43 beads is often marginal at best; depending on how much RF you are trying to suppress you could possibly need as many as 20-25 of them (really!!) to truly suppress the RF on the coax.

For another thing, the tuner end of the coax is the wrong place to put the beads; they should be at the antenna feedpoint end. If you're going to do that, though, you're far better off with a 1:1 choke-type (current) balun or unun. I use 20 beads on my extended double zepp feedline only because I had them and did not have a spare 1:1 current balun, and they work pretty well (which is to say, well enough) although the choke balun would have been better and I will probably change it in the spring.

Make sure the ground stud on the autotuner is grounded with a fat lead as short as practical; don't depend on the shield of the coax jumper to the rig to provide the ground.

Finally, the power cable to the tuner should be looped several times through one of those #43 beads you have. I did have issues with my autotuners at higher power (500+ watts) until I did that.

I'd still like to hear some more opinions about the RT-600 remote tuner. I am a long time LDG tuner user (going back to when several units (I think the original AT-11MP and Z11) came out as kits. My first choice for a 500-w class unit , however, would be the Storkcorner 1-KW unit from the Netherlands. The built quality looks very impressive. However with exchange rates and shipping it is almost twice as much as the street price of the RT-600. And then: what if it needs to be sent back for servicing (nothing's prefect)? $150 round trip shipping.

So I hope a few of you have enough good/bad experience with the RT-600 to be able to help myself and others make a purchasing decision. My main use of the antenna will be a 43-ft 80-10 multiband vertical.

Oh yes: Merry Xmas and Happy New Year!

David, I've been using the RT-600 since March feeding a 20' Aluminum flagpole with about 1300 feet of ground radials. Due to the HOA, that is about the best I can do. But I have used it on 40-10m and it also matches six real good but no sigs here. Recently (last couple of months) I've switched out the aluminum for fiberglass and helically wound about 35 feet of copper on 1" PVC inserted inside the 20 feet of fiberglass. Feeding 100' of RG-213 using Palomar Engineers 5 toroid coils for at the base for RFI Choke and a current Choke at the ICOM 7410/Ameritron ALS-500M.

I have been more then happy with the RT-600, but sometimes it takes some time to get a match after changing bands. It doesn't always keep the freq in memory as claimed. I have used local tuners when I wasn't running the Amp but find there was too much RFI with the long Coax run and went to the RT-600 when I started using the 500W Amp. No complaints. I do cause lots of RFI using 80M if I get a match so only use 80M very late at night. All in all, I would highly recommend the RT-600. Will probably have one for sale here shortly as I have a small Steppir Vertical I will be putting inside the fiberglass flagpole after the first of the year. Have the ground mount ready to go and just need to switch everything around after the first of the year.

Hope this helps you,

Bob/KH6Y

Hi all I would like to know if this is normal.... When I hit tune on the IC-725 the tuner (LDG AT-100PROll) starts doing it's thing then stops because its tuned however the little notice on the IC-725 display says THRU, I checked the tuning by transmitting and seems to be in tune according to the tuner....is it because the tuner is not the Icom AH-3??
The manual says when the AH-3 is used, a TUNE notice appears on the display when in tune..and THRU when it cant find a tuning solution.
I would like to know....

I would take the AT-100's word for it. The Icom is built to work through the Icom tuner. Look on the face of the 100. If it cannot find a solution the "Bypass" light will glow. As it has a PWR and SWR meter on the front, you can see if you have power out, and how much is reflected.
Do you have the tuner cable that attaches from the Icom to the tuner? Even if you do, the tuner will not communicate with the rig as the Icom tuner would.

From: tim.forrester@...
Topic: 7656 Message: 7656

A friend of mine thinks he has fried one or more relays on his IT 100 auto tuner.

Is there a way to test the relays in circuit or even out of circuit to determine which ones need changing ?

I have a well equipped test bench / workshop, but not sure of the best way to determine what's failed.

No obvious burn marks anywhere.

FYI he was using it to tune a 50MHz vertical to the 70MHz band so well outside it's tuning range but did work for a short while !

I'm located in the UK so 70MHz is allowed.

Follow up question - assuming I find which relays are toast, where might be the best place to order some from ?

Thanks Tim G4WIM / KT6UK

From: tim.forrester@...
Topic: 7656 Message: 7657

Ok found a way and identified the relay, here's what I did. I first removed the controller chip such that I could drive each relay independently from an external 5 V PSU.

I then applied a low level 14MHz signal at the input and monitored the RF output as I switched relays in and out expecting to see the signal level change at the output.

I noticed that each relay clicked apart from K4 which was stuck.

Took it off the board and confirmed it was stuck then cut it open and sure enough burnt contacts.

Now just a matter of sourcing a new relay along with a few spares just in case !

From: keith@...
Topic: 7659 Message: 7659

Wanted to take a bit of bandwidth to introduce myself. Name is Keith, call sign KN5G, located in Henderson, Texas. I have used a LDG AT-1000ProII with a Yaesu FT-857 and Ameritron amp on HF for many years with great success on non-resonate wire antennas.

I recently up-graded to a Yaesu FT-991, which I like so far but have not been successful in figuring out how to use the AT-1000ProII with the FT-991. Hoping someone has already crossed this bridge and can offer some suggestions on how best to use the AT-1000ProII with the FT-991.

Yeasu support replied that the FT-991 does have a REM/ALC jack that will accept an External TX request.

I would expect at the very least to have to set the Tuner Select option in the FT-991 to External. Could it be as simple as plugging in the two conductor cable, (that I used for the FT-857), into the External TX request jack on the FT-991, and pressing and holding the TUNE button on the AT-1000ProII?

I have to say the Yaesu manual for the FT-991 is sorely lacking in detail, but I'm hoping I can still use the LDG Flagship tuner with the new FT-991.

Thanks,
Keith - KN5G

Thanks for the reply Ed. The FT-991 is a bit different from the FT-dx1200. It doesn't have the same I/O signals, at least not on the same ports. I did manage a solution and have posted a link to a short write-up explaining what I came up with.

Thanks again and Happy New Year's !

The connections were specific to your FT-991 but the end result's the same. Good solution and thanks for posting. I need to create a similar document on the FT-dx1200/AT-600Pro but I have no knowledge to do that in a PDF.

7674. Adding a power switch to the Z11 Pro2 ?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-01-05 13:29:11 UTC
From: rmckee1957@...
Topic: 7674 Message: 7674

Since the tuner has latching relays and supposedly holds the tune settings when power is disconnected, has anyone added a power switch to their Z11 Pro2 ? Mine will not hold tune on 17 meters for some reason and I do not want to pull it out to disconnect the power cable each time I use it on that band and would rather just have a power switch on the front panel so that once it is tuned, I can turn off the power to lock it in the tuned mode. If anyone has done that I would love to see some pictures of the mod. I could probably figure out a way to do it providing there is room to mount a switch on the front panel but would still like to see some ideas first. In my opinion a switch should have been included in the first place.

Why don't you just use the semi auto mode? It would require you to
manually hit the tune button but would keep the tune locked in.

Got it set to semi auto mode but on some bands (17 meters is worse) it tunes but then starts retuning once you start talking and the power level comes up. Using it with an Icom 706 Mk2 where the power drops to 10 watts in tune mode, but when the power comes up to full it starts retuning. A power switch would solve the problem completely !

If it starts tuning when you talk you are either:
1. not is semi auto mode
2. have enough RFI to be causing problems with the tuner.

It sounds like you have a RFI issue you should look at. Are you running
any chokes on the coax and the power lead?

I installed a toggle switch just above the power connector on the rear panel of my Z11ProII for a different reason. If I use my Comet CF-706 Duplexer with my FT-857D the tuner goes wacky trying to tune when I'm using my radio for 2 meters. It sits there chattering away even though the 2 meter RF is theoretically bypassed. I'm sure it is due to RF getting into the tuner from a less than perfect Duplexer but rather than try to find another cure the switch is an easy cure, plus since I don't use this tuner very often it keeps the internal batteries from draining when not in use. The switch is simply wired in series with the battery pack.

I'm wondering if there is room for the switch on the front panel, will pull the cover when I get home to see but I'm trying to prevent the need to pull it out to turn it off. I run it from the control cable that connects between the 706 and the tuner - no battery pack in mine. I may make a cable with an inline switch that I can mount in an easy to reach location that connects between the tuner and the power cable if there is no room to mount a front panel switch.

Sorry about that. I thought the 817 had the same connector. Looking though the manual for the 817 I don't see any way to make the 817 interface with the Z11 to do one button tuning. You would need a CAT tuner that actually sends CAT commands to the radio to make it switch modes.

The good news is the Z11 really doesn't need to interface to the radio to work. It will auto tune as soon as you transmit in the auto mode or you can control when it tunes using the semi auto mode.

Before you completely give up I would add 10-20 feet of coax or more to the antenna line and see what happens. I've seen this fix some problems where the antenna is not quite resonant and the antenna tuner is trying to fix some odd L/C combinations. It's worth a try and easy to do. <snip>

The antenna is only about a 2.5:1 swr to begin with in the portion of 17 meters where I had the problem. It seems with this tuner I have worse problems with it the closer the antenna is to being matched to begin with. If its over 3:1 swr, it will match it and stay matched, around 2.5:1 it will find a match then start tuning again or at least read a higher swr when you transmit with 100 watts.

W4RT.com used to sell a device called “One Touch Tune” which is no longer sold. A connector plugged into the ACC jack on the radio and had a jack to plug in whatever you would have had plugged into the ACC jack so you didn’t lose functionality of the ACC jack. There was another jack that you plugged in the cable like the one used for the 857. I had a OTT that I used with my Z11ProII when I had my 817 but I sold it some time ago. You can go to W4RT.COM, select reviews and manuals, select W4RT, then select OTT which is at the bottom of the page for a better description than what I gave. You might keep your eyes on eBay to see if one pops up.

The best way to use the AT button on a Kenwood transceiver is to use a KT-100 tuner. Mine works great with my TS-480 and TS-590, so it should work with your TS-2000. I seem to recall that LDG once had a Kenwood adapter, but it was kinda pricey and they discontinued it years ago. Maybe you could find one those used, but I seem to recall it only worked on certain specific tuners so you would have to check that out. Also, my experience is that the KT-100 is somewhat sensitive to RFI, so I have a lot of ferrite beads on each of the three cables going to it, and it seems to work much better this way. 73,

W4RT.com used to sell a device called “One Touch Tune” which is no longer sold. <snip>

Thanks for the advice, I've searched for a schematic on it but they are very stingy with that info ! Not really a big deal as I can just transmit a carrier to get it to tune, just thought it would be much simpler to push one button and have it done like that. When I get time I will set down and see if I can make it do it somehow, til then I'll keep searching. May even get an Elecraft T1 tuner for the 817 !

I spoke with W4RT at Dayton one year and they said that the product was microprocessor controlled and very complicated to make work. They had problems with it and discontinued it for that reason. They recommended the LDG specifically made for the 817 as the way to go. I wish I had bought one when I had the chance.

Good morning all, just happened upon this message about the RT-600.
I have been using this remote tuner since about the summer 2015 without any incidence to report. I seems to works as advertised. My setup is a KX3/KXPA100/KPA500, 500 Watt amplifier connected to an 80 meter dipole up about 25 feet. I tune the dipole on 80/30/12 meters with the tuner giving me 3 bands. If I had another one, I would connect it to my 32 foot vertical for all band coverage on 40/15 meters. I am using coax for all connections (RG-213).

If you go to my webpage at k5pa.com/Ham%20Radio/HamStation2015.htm
http://www.k5pa.com/Ham%20Radio/HamStation2015.htmyou can see photos of the installation.

I have never taken the remote section apart but I am tempted to for photos but imagine it is much like their other tuners (which I own a number of).

Good luck,
73 Gene K5PA

They recommended
the LDG specifically made for the 817 as the way to go. I wish I had
bought one when I had the chance <snip>

Probably so, but the tuner that is made for the 817 doesn't have the matching range that the Z11 Pro2 does. Oh well, my homebrew manual tuner will match anything I throw at it !

7694. Using LDG-1000 Pro II with Yaesu FTDX-3000?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-01-14 19:27:59 UTC
From: Neal Pollack
Topic: 7694 Message: 7694

Hi:

I just purchased this tuner to use with the Yaesu FT-DX3000.
I notice that it (tuner) does not interface to my HF transceiver to automatically
change bands when I switch bands on the transceiver. So until I transmit
a carrier, it will not retune and switch bands, so receive does dead.
I find this awkward, because in order to re-tune it to the new band, I need
to pick a quiet, unused frequency on the transceiver, set mode to AM or CW,
and then transmit at 15 to 20 watts. But until I do that, I can't receive on
the new band, so I can't tell what frequency is not in use :-)
[Yes, I know, silly newbie...]

What tips, tricks, schemes, or custom interface ideas have people come up
with so that it is less tedious to change bands and retune?
I am especially interested in that I heard about some people making a custom
cable or mod so that they can avoid the "change mode, dial down power, press tune,
change mode back to SSB, dial power back up, etc" every time I change bands
hunting for QSO's?

I am sure this is just something in the learning curve?

Cheers,

Neal

I use an AT-200pro on my FTdx3000 using a simple switch something like the one described here you simply press the switch and the ATU tunes (more a case of it recalls a tune value from memory) in a fraction of a second literally each time you change frequency or bands

With our location being smack in the middle of the east coast blizzard, shipping has already been affected. The “Exception” e-mails form UPS have been coming in all day. With the snow amounts that are projected and our rural location, we would expect incoming and outgoing shipments to be delayed by at least four days.

Hopefully, it will all be cleared out by mid next week.

Everyone be safe,

Dwayne Kincaid

1.Check the relays for continuity both activated and non activated.
2. Check for a burnout inductor by burnt appearance or continuity.
That will get you started.
Buy the way if you find a source of schematics let me know please. I have 3
and
they all work great. Of course the one I use most has to be reset (powered
off
then on)most often from lighting in the area or just stormy weather. I have
pounds
of torids on all the conductor going to it and that helps a lot but then
not a
total fix.73, Larry

I think I have an issue with my LDG1000pro AT. For antenna 2, the tuner doesn't seem to work any more. It cannot get any antenna even very well resonant antennas to tune and it reduces receive levels dramatically. On antenna 1, it was working fine but now is doing the same thing.

I have tested all antennas with my AA54 and they appear to be working fine. They also are fine without the autotuner in line. Any recommendations on troubleshooting would be very much appreciated.

7707. Using RT-RC-100 and RBA-4-1 to tune long wire

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-01-31 22:51:16 UTC
From: w_r_adams1@...
Topic: 7707 Message: 7707

I've ordered the RT-RC-100 RBA-4-1 combination for use with a 90' end fed long wire (kind of a lazy inverted L at my site). I have questions about actually wiring this combination at the antenna. From reading the manual, I assume the antenna wire is connected to the red terminal of the 4:1 balun. So my question concerns the black terminal of the balun and the ground lug on the RT-100. Is there a requirement to wire them together? Does the wing nut/lug connect to a ground rod? Should an antenna return/radial/counter poise be attached to the balun?

In anticipation of the promised Wednesday delivery and taking advantage of our nice 60 to 77 degree weather I hung 90' of wire and made a temporary outdoor installation using my old AT-100Pro, an LDG 4:1 balun and a couple of homebrew bias Tees this weekend. No counterpoise was deployed but the AT-100Pro was grounded to an 8'copper clad rod that is attached to the home grounding system. A double male UHF connector tied the balun to the tuner's output port 1. Using my shack transceiver at 25 watts output, this system was able to tune 80 through 10 meters, except the 15 meter band, to less than 2:1 as indicated by the transceiver SWR meter. No field strength readings were made as this is a mockup of the coming equipment. Several phone contacts were made on the 40 and 20 meter bands and subjectively this system is quieter than my existing under soffit 80/40 fan dipole. Received signal strength was better on the end fed wire also.

I chose the 90' length based on an L. B. Cebik paper on the inverted-L that presented a range of expected impedance values and a comparison of those values to the specifications for the RT-RC-100 / RBA-4-1 matching capabilities. As installed, neither the vertical nor horizontal legs meet the model nor is the wire clear of vegetation. The result is I hope this system will provide contacts at my location.

I am also interested in the answer to a question posed to this group on Jan. 20 about bypassing the autotuner for SWL use of the antenna. I hope there is an answer other than installing a bypass switch at the tuner!

From: wellfj@...
Topic: 7708 Message: 7708

I am running a LDG200II Pro which has been operating fine, however, now the tuner only outputs 5watts on any power setting of my radio 0-100watts on any HF band. I checked the output on the radio with a meter and the radio is fine. I still see SWR readings on the tuner 1.5 or less but output is pegged at 5W. Has my tuner gone down and is there anyway to trouble shoot? Any thoughts?

The first thing I would look at is the power cable, fuses, etc. It looks like the tuner is trying to power up, loads down the 13.8VDC line (bad fuse, connection, connector?) and shuts down because the voltage sags. It then repeats the cycle. It may be something else, but this is the first thing and simplest thing that comes to mind.

Try to just see if the tuner works. Put the radio in AM mode, manually transmit, start a full tune and keep transmitting until it stops. If that works you probably have a problem in the radio setup menus or a bum cable.

If the Z11 ProII tunes with manual keying, this means 99% is working okay and the issue is just the radio/tuner interface. The tuner coming out of sleep is not the issue as the tuner comes out of sleep the moment you press a button. The tune command logic is not sent to the radio until you release the button and as can be seen in your video the tuner LEDs are still on after release so the tuner uP is awake. The radio should immediately change modes and transmit but it is not.

Which radio are you using again? Are you sure there is not a menu setting required? It is possible Yaesu changed something if this is a new radio. On many yaesu radios one had to change a menu item to indicate you are not using the Yaesu tuner which I think was the default. You might want to at least give that a try.

I wrote the firmware for the Z-11Pro but unfortunately don't know what was changed in the Pro-II as I have not been directly involved for some years. The stereo mini plug interface is as easy as it gets. I do have permission from LDG to help out here as much as I may not have the latest information.

In any case please experiment with my above and let me know the radio model and I'll see if I can get some additional information for you.

I'd like to also add that you might want to pop the cover off the tuner and put a DMM on the "tip" of the "radio" jack on the tuner, the other DMM lead to the tuner case.. This is an open-collector logic drive to ground with 0.01 uF bypassing and no pull-up. The radio should pull it high when the tuner is idle. If you see this go low when you release the tune button on a memory or full tune, you know the tuner is doing its job and the radio is not recognizing this simple logic signal.

Let me know what you find and also after playing with the radio menu some along with letting me know what Yaesu you have.

Dale,

Thanks for the additional details. Yea that is just not right (press another button and then press tune it works properly)!

What kind of power supply and cable length are you using to power the tuner?

I have a few other ideas to try:

1) Try connecting the power cable directly to the power supply or try a different power supply. I don't know if you are using a Power Pole type distribution box.

2) If you have a different power cable, try that, first direct to one or two different power supplys. If you have a 12V SLA battery laying around, try that.

3) If none of the above works and you have some "junk box" parts and a power cable to sacrifice, try putting an electrolytic across the power cable close to the tuner as another diagnostic tool. An electrolytic, 15V minimum and maybe 250 uF or greater, 1000uF or some Std value near that would be ideal

None of the above should be required and I have never seen anything like this. There is something not right going on here. I wish I had specific knowledge on the changes to the Pro-II. After you get back on the above, if it is still not working, I'll try to get you some inside help.

Craig

I mostly operate qrp, but some 100 watt level. The Z11 Pro works down to 0.1 watt correct? Anybody use it qrp?

John

Hello John,

I use mine with a FLEX-1500 to tune my 43 ft vertical. It tunes easily with one watt. I installed a battery holder and have used it portable, also. It has been very reliable.

73,

Phil N3ZP

I looked at your video again and this time notice the green/red LED on the radio and see that it is keying the radio every time so please scratch what I had previously typed.

The tuner is working the way it was designed. Even on a full tune, if the match is already below the threshold (excellent match) it exits the tune algorithm early as it is already tuned. We did it this way purposely for speed. So for example, even on a full tune, it will take a shorter amout of time if the antenna is close to tuned and a longer time if the antenna is far off. Again, this is by design.

In your case the relays are already tuned so it is the extreme case that even a full tune exits "early" at no additional tuning. As the tune memories get filled with the settings for your antenna across bands and frequencies, this quick tune will be come more likely, again by design for speed and convenience.

The reason that sometimes it clicks once or twice when you press over and over quickly is just because the initial SWR reading shows just above the excellent tune threshold so it starts to tune and within a couple relay adjustments it is done and stops tuning.

If you do a bypass and go to a band and Freq it has not tuned before you will discover it will act more like you are expecting.

If you have a good dummy load connected, it will act like this all the time!

Both tuners you received are working as designed and properly.

73,

Craig

7732. Using Winmore with Icom IT-7100 and IT-100

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-02-21 20:21:14 UTC

Hi all,

I'm a new ham (about 6 months) and trying to wrap my head around sending and receiving Winlink 2000 email via HF. I'm using an Icom IC-7100, RMS Express, and Winmor. The specifications in the IT-100 tuner manual say I'm limited to 30 watts on PSK and digital modes. I'm assuming this also includes Winmor.

Questions:

The Icom IC-7100 allows me to set the RF power between 0-100%. Since the maximum RF power for HF on the IC-7100 is 100 watts (running barefoot), do I simply set the RF power to 30% and my IT-100 will be safe?

If I put the IT-100 in bypass mode but still have it connected between the IC-7100 and antenna, do I still have to stay at or below 30 watts for digital modes, or can I go higher if needed without risk of damaging the IT-100?

Thanks in advance,

John

How much power does it take to communicate with the gateway, I think they call it?

I've not run Winmore on HF, but the emergency group in Coronado had a Winlink VHF FM set up we used regularly. The transmissions were very short, and a watt was more than enough, depending on your antenna, of course.

Try 5 watts and go from there. I imagine it is somewhat dependent on propagation.

Digital modes heat up finals (and antenna tuners), so it is a rule of thumb to set the transmitter to 30% power out. Many digital modes require only 10 watts or so, or you overload the signal, and the receiving station won't like you much.
Digital transmitting is dead carrier at 100%, and most modern rigs won't take it. Note that CW and SSB are only about 50% duty cycle.

Thank you guys.

I emailed LDG support and was told the stated RF power limits do apply when the tuner is in bypass mode. That answer seems obvious now, but I just wanted to be sure about it. So with the IT-100 tuner physically connected between my radio and antenna, I'll always limited to 30 watts when using digital modes having a 100% duty cycle.

I did wind up setting my Icom IC-7100's RF power to 30% (30 watts) then adjusted Winmor's settings so the max reading during sustained xmit on the radio's RF power meter is about 25% (25 watts). That gives me an RF power comfort margin and seems to be working very well when sending data.

Most modern rigs are also limited to a 30% power when on a 100% duty cycle. It has been the case for years. I have owned several rigs and even the tube rigs like a Hallicrafters HT-32A, a Swan 500, a Drake TR-4, all ran at a reduced power when on a 100% duty cycle, which for these was AM.
It is not just the tuner!

Hi Craig,

I have tried it on an antenna which was not tuned and the same thing happened, tried other bands and still the same.

Also tried yet another one and it's the same, so mine has gone back and a few others are going back to the dealer as well.

We have cancelled the other for the PRO 1000 and gone with SGC now.

I'm sorry to hear. It seems like fast (in this case, instant) tuning, whether from memory or a prior close match on a full tune, is not a good for your application.

I'm sure LDG could have made a full tune always QRM a Freq for some seconds of relay clicking sound but decided not to within its algorithm to early exit once a low SWR is found.

My original thoughts are pasted below.

Regards,

Craig

I looked at your video again and this time notice the green/red LED on the radio and see that it is keying the radio every time so please scratch what I had previously typed.

The tuner is working the way it was designed. Even on a full tune, if the match is already below the threshold (excellent match) it exits the tune algorithm early as it is already tuned. We did it this way purposely for speed. So for example, even on a full tune, it will take a shorter amout of time if the antenna is close to tuned and a longer time if the antenna is far off. Again, this is by design.

In your case the relays are already tuned so it is the extreme case that even a full tune exits "early" at no additional tuning. As the tune memories get filled with the settings for your antenna across bands and frequencies, this quick tune will be come more likely, again by design for speed and convenience.

The reason that sometimes it clicks once or twice when you press over and over quickly is just because the initial SWR reading shows just above the excellent tune threshold so it starts to tune and within a couple relay adjustments it is done and stops tuning.

7740. Voltage measurements on RC-100

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-02-29 20:38:11 UTC
From: w_r_adams1@...
Topic: 7740 Message: 7740

I recently purchased an RC-100, RT-100 4:1 balun combination. Unfortunately this combination failed to tune until I substituted a home brew bias T for the RC-100. I made the following voltage measurements on the RC-100 prior to deciding to return it for repair or replacement:
At power plug into RC-100 12.45V

At Tuner port of RC-100
Unit ON 7.32 V
Unit OFF 1.48 V

At input to RT-100, approximately 55' of LMR400
Unit ON 7.32V
Unit OFF 1.403V

After substituting my homebrew bias T, the voltage for 12.45 VDC input measured the same (12.45 VDC) at the T input and at the tuner end of the transmission line. The substitution also allowed the system to tune my 90' wire on all HF bands.

What voltages do you have on your RC-100 port in the on and off states?

This is simply curiosity as I am not doing the repair, I returned it to LDG as stated for repair or replacement.

I understand that this model goes into Bypass mode when turned off. However, does it also default to one antenna or the other when it is off?

For example, I have antenna 2 selected when I power down the unit. Does it remain on antenna 2 in bypass, or does it default back to antenna 1?

Hi Folks! --- Hope someone can help.

This is the first time I have tried to fire this combo up.
My problem is that as per the LDG directions I try to go into menu item #19
and set the CAT rate, there is no menu item #19 it goes directly from 14 to 22 and I have no idea
as to why.

Any guess's or solutions would be much appreciated.

Thanks in advance

Select Menu option 001 EXT Menu, this will open up more detail in the menu options and you should see cat rate setting once you set it to the extended menu.

Doc,

Here's what I have found with my AT-600Pro... I am assuming that they would be the same but... ?
Selected Bypass and ANT2 (both LEDs lit).
Powered off.
Power on & it came up with ANT2 LED lit.
Selected Bypass (Bypass LED lit).
Powered off.
Powered on & it came up with ANT1 LED lit.
Powered off.
Powered on & it came up with ANT1 LED lit.
I'm assuming that ANT1 is the default.

Is this what you're looking for?

from the manual:
"The power button on the AT-200 ProII actually places the tuner in bypass and enters a low power
sleep mode, rather than turning the unit fully off. Press the Power button for 3 seconds to turn off, or momentarily to turn on. By default, the tuner turns on at initial application of DC
power. When the tuner is off, the antenna selection defaults to bypass with Ant 2 selected."

Hope this helps

Maybe. According to the manual, bypass is not remembered from power down to power up. It may still be correct, however. Mine appears to default to antenna 1. The key I'm looking for is which, if any antenna is default when the unit is _off_. In other words, is there any way to use antenna 2 while the unit is off?

Time for an experiment. In the past I've had my vertical connected to ANT1 and a dummy load to ANT2. I just switched those and found that ANT2 is connected when the tuner is turned off. If ANT2 is active (light's on) and I either turn the tuner on or bring it up when I switch on my station PS the tuner comes up with ANT2 active. My 600Pro recalls the antenna last used and when selected, ANT2 is usable when the tuner is turned off. Test this with your 100Pro... if you can hear the stations on the air on ANT2 with the tuner turned off then it's working the same as mine.

BTW... I really goofed when I initially gave you my findings... I said "Powered on & it came up with ANT1 LED lit." Correction... That should have been "with the Bypass LED lit." I've been ill and my thinking was muddled. Sorry for any confusion to anyone following this thread.

7758. YT-1200 tuning for FT-991 failing

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-03-13 09:41:13 UTC
From: kuocliao@...
Topic: 7758 Message: 7758

Dear LDG group:

Just bought a YT-1200 and installed with the Yaesu FT-991, following the instruction to install and set CAT rate etc. I operated it by pressing Tune botton for 3 sec. and LED goes out for one blink, several cycles went smoonthly, I can see the SWR was nearly 1.1. I was very happy. Then after few tunings I found the tuner failed to tune all bands and after I pressed Tune the tuner did not tune and the LED was blinking five times-according to the manual , it means "the tuning cycle failed. no RF was detected".

Need advice to troubleshoot if there is anything wrong with the setting or tuner itself, feel frustrated on this error.

Thanks and 73s

From: tittiger@...
Topic: 7759 Message: 7759

Hi!

I am a very new general license holder and have a Yaesu 857D/LDG YT-100 setup.

When I tune some of the time the relays (in the radio?) must chatter at least 1,000 times! On the lower frequencies 160 and 80M I can not do just a memory tune and the YT-1000 goes into full blown tuning even though I let go of the button as soon as the red light comes on.

(I realize that it probably can not get a good tune at these frequencies but the algorithm stinks in that it does not do what I tell it to do. -- Why can't it just flash out that there is no tune in memory and let ME decide if I want to do a full blown tune? Are you listening LDG?)

My question is, how tough is this on the radio? Are these relays designed for this kind of use?

If they go south how hard are they to change out?

Thanks in advance

KD0ZBM

Topic: 7759 Message: 7762

On 160 and 80, antennas typically have extremely narrow bandwidth, and fine tuning touchups are required even for a very small change in TX frequency across the band. The LDG is indeed telling you, by insisting on doing a full tune cycle, that a memorized setting, even though for a frequency close to the new one, are not right for the new freq you've set, and a full tune cycle is needed. If you later go back to exactly that same frequency, the memorized tuning setting should kick in quickly.. One could use up a lot of the LDG's memories just on 160 and 80. The algorithm doesn't stink. The LDG is not doing what you would like it to do in this case because it's protecting your radio from a too-high mismatch, and keeping it from destroying itself. If you want to take control of that, then don't use an automatic tuner.
The chattering relays are the LDG tuner switching inductor and capacitor combinations to achieve best match. Normal. If your antenna is outside the range that the LDG can compensate for, it will stop the attempts. On your Yaesu you might also see a "High SWR" indicator on the radio's LCD display. If there are chattering relays inside the radio itself, I'd be rather concerned. By experience it could indicate an RF feedback condition, another whole discussion in itself.
I assume you meant YT-100 not 1000. The LDG manual very clearly explains how and why the unit works, and how to interpret the readouts that the red LED indicator provides.
I'm using the AT-897Plus with FT-897D.
73, good luck.

Chuck WV8A

That helps a bit but I want to know what the algorithm is thinking when I call for a memory tune, b ituy refuses to do so and does a full blown tune instead.

I suspect it does so because the SWR is poor at that frequency that it overrides what I want.

I would like to suggest to LDG that they consider changing that behavior and instead alerting me that the tune is very poor at that frequency and allowing me to make the choice as to whether I want a full tune or not.

They might see that as a feature. I do not. I see it as a bug in the software.

I guess Ideally I would like to be able to modify the behavior of the tuner to better suite my needs. I am not sure if the unit makes that possible with an EPROM or other alterable type of memory.

I am sure that one of you reading this probably knows. :-)

7765. Tune when listening?

Date: 2016-03-16 12:01:53 UTC
From: tittiger@...
Topic: 7765 Message: 7765

This is probably a rhetorical question, but I will ask it anyhow since I have never seen it explicitly stated.

I assume that it is just as important to tune when I am lurking and not transmitting, , as it is when I transmit.

The difference being that you can not damage your radio when trying to listen with a very high SWR, but you sure could if you transmit with a very high SWR.

I am close to being correct?

Thanks

The same losses occur with a mismatch on receive as transmit. I guess it doesn't "hurt" the radio.

Try this. Put your radio on a different band/frequency and listen for signals, then do a "tune." Noise and signals ought to be noticeably louder.

The LDG tuners call for a full tune whenever the SWR at a frequency is over 1.7 and it has not tuned that frequency before. If it has tuned that frequency, it will be stored in memory, and will make only a "pop" to get there, or at most a "pop-ping".
Asking the tuner to wait for input from the operator is not really a good idea, as many operators will keep whanging away, even at high SWR, thus burning the finals out of the radio. A costly mistake.
The tuner does just what it is designed to do, and is working as advertised. You can press the key combination of <FUNC> <C Dn> and make it not tune until you hit the <Tune> button, as shown in the manual, but then it becomes more of a manual tuner.

It could be either. For the Yaesu, you have to choose a menu item that chooses an external antenna tuner, and use a specially made cord that interfaces with the radio.
The tuner will sound like a can full of steel shot being shaken, but that is how it is supposed to sound, and can sound like that for what seems like a long time. If the relays are chattering on the radio, then you need to go to the manual and figure out which menu item needs changing.

Well, I would (and usually do) find a clear spot on the band and let the tuner run a tune cycle. I use a balanced wire antenna, and the tuner seems to make a difference when I do this. I imagine it would make no difference on a coax fed antenna.
Remember that the tuner is no more than an impedance transformer. It does not, in most cases, resonate the antenna. The antenna's characteristics do not change with the tuner. This may be different when it is a balanced wire antenna, but I doubt it.

I have a 20 meter dipole. I usually use my 102' balanced wire fed doublet. It is like a G5RV, except for balanced line all the way to the shack. The tuner HATES 17 meeters on the doublet. It balks and will not tune, and the receive is poor. I can switch to the 20 meter dipole, run a tune cycle, and receive comes up 10 dB, and I get a 1.1:1 SWR! The antenna is cut for the phone portion of 20, but works just fine on 17. As a matter of fact, I worked San Andres and Providencia on 17 last week with this configuration. I don't think my losses were that bad, and the tuner worked fine.

Is it the Tuner that usually makes the chatter?

If so I am a bit relieved. I would rather have the relays on a $150 piece of equipment, that was probably designed to do so, that that kind use use, rather than my radio.

Perhaps I missed it but...
What is your antenna type and it's feedline? Sounds like a simple question but there many variables and helpful to have all the facts pertaining to your complete antenna system.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } There is no internal tuner in the FT 857 so relays clicking in it would be bad.

I own an old ICOM AH-2 tuner that could tune a foot of wire on 20 meters. That might seem like a good thing, but it isn't. Why?

One day, the tuner stopped working while I was operating on the way to work. When I got home that afternoon, I opened it up and found a copper trace burned out on the tuner; the trace was far too thin – poor etching*, perhaps – but I suspect it would've burned out if it had been full width.

By using inductors and capacitors to alter the ratio of current to voltage. They are resonant circuits, in a manner of speaking. And what do we learn about resonant circuits when we study for the test? The current in a resonant circuit can far exceed the current sent into it; the current flowing around a parallel resonant circuit is many times higher, if the Q is high enough, then we might think of from the voltage we applied to it.

Trying to tune a very high impedance, perhaps a half wavelength of wire (which tuner manufacturers tell us not to do), will cause current in a tuner to be much higher than its traces and inductors can take – and the voltage across capacitors can easily exceed their ratings. One day, the tuner stopped working while I was operating on the way to work. When I got home that afternoon, I opened it up and found a copper trace burned out on the tuner; the trace was far too thin - poor etching, perhaps - but I suspect it would've burned out if it had been full width.

That's why LDG (and now others) program their tuners to stop tuning if the match is out of the range the components can handle. By using inductors and capacitors to alter the ratio of current to voltage. They are resonant circuits, in a manner of speaking. And what do we learn about resonant circuits when we study for the test? The current in a resonant circuit can far exceed the current sent into it; the current flowing around a parallel resonant circuit is many times higher, if the

Q is high enough, then we might think of from the voltage we applied to it. That current, flowing through the capacitor and inductor, produces an extremely high voltage across them. We don't want our L match or T match tuners to even approach parallel resonance.

Trying to tune a very high impedance, perhaps a half wavelength of wire (which tuner manufacturers tell us not to do), can cause current somewhere in a tuner to be much higher than its traces and inductors can take – and the voltage across capacitors can easily exceed their ratings. One day, the tuner stopped working while I was operating on the way to work.

When I got home that afternoon, I opened it up and found a copper trace burned out on the tuner; the trace was far too thin - poor workmanship, perhaps - but I suspect it would've burned out if it had been full width.

That's why LDG (and now others) program their tuners to stop tuning if the match is out of the range the components can handle. Relays too have ratings; contacts can be scorched, welded together, or pitted by too much current flowing in them or too much of voltage arcing across them.LDG – and others – design tuners based on the RF power and modes most amateurs use. This usually means SSB, sometimes CW, and lately, high duty cycle data modes. The "200 W" tuner we buy may be built for a rather lower continuous power and using it very long at even a 100 W may exceed component ratings; if, in addition, we try to tune a load it is not rated for, we're asking for trouble.

And that's why a firmware limit on the matching range attempted is a GOOD idea.

The antenna and feedline has everything to do with your question as this will determine return-loss and Q of the antenna. Especially on low bands, good, new, short transmission line and a high Q antenna will be harder to match without a longer tune sequence.

Craig

Joe,

Before analyzers came on the scene I used a SWR meter and when needed a grid dip oscillator. I built a lot of antennas using just the SWR meter before I built the GDO.

Your SWR meter will tell you a lot about your system. Use that to check out your antenna system from the station end of the coax, without the auto-tuner to the antenna, on the frequencies of interest. If you don't have a separate SWR meter then use the one in your rig. If it pegs your meter on the frequencies the antenna manufacturer says should be near resonant you will have to track down the part that is at fault. Your rig wants to see an SWR equal to or less than 1.5:1.

I might just have to think about a SWR meter for now. :-)

Thanks everyone for all the input. I will take the time it takes me to save my pennies to get more educated as to what is one the market.

7789. Yaesu FT-847 tuner question

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-03-19 23:05:03 UTC
From: n9nau@...
Topic: 7789 Message: 7789

Is there a LDG tuner that will interface directly with the Yaesu FT-847? I was wondering if any one out here has done this and what did it take to do it? I know there was an automatic tuner Yaesu FC-20 and the ATAS-100 that Yaesu sold for directly interfacing with the FT-847.

I have been able to use the Z-100 PLUS with special procedures during tuning to make it work. It was purchased with my FT-857 and worked quite well. I purchased a YT-100 thinking it would replace the mechanical tuner on the FT-847 but I could not get it to tune. The YT-100 works fine with the FT-857 so I left it there. When I tune the FT-847 and Z-100 I have to set the FT-847 up as either AM or FM when it transmits to fool the Z-100 into tuning. When I press the tuning button on the front of the Z-100 it will then key the transmitter via the CW input lead and do its business. Then I have to change the transmitter back to SSB to work signals. So far this works fine, but I am wondering if there is an easier way.

My reasons for this is Field Day when less familiar people try to operate on your equipment position while you are catching a nap or something. The mechanical tuner I have been using has switch problems and doesn't work well on the 160 meter band.

Any info would be quite helpful since this is my first time trying to use this. Thanks

N9NAU

I find it hard to believe that LDG did not provide a way to do a full reset. Once my LDG Z11 Pro 2 has been used on a frequency with a certain antenna, I find it impossible to get it to tune another antenna on that frequency. I can confirm this by letting it try to tune the new antenna for which it doesn't find a match and then just switch to the original antenna and its matched without the tuner making any changes - it just wants to do a memory tune for the original antenna only. I can force a full tune but it will not hold it and returns to the memory tune on the second transmission. Anyone else had this problem ? I feel that it needs reset to factory default but according to LDG there is no way to do that !

My older LDG-AT200pro can do a reset. My LDG-AT600 proII does not. It was confirmed by LDG. I was told the newer proII models clears memory when you do a full scan on a given frequency ex: holding the tune button for more then 1 second will initiate a new memory scan...

Hope this helps

Given the black & white conditions that you describe and I am an engineer (forgive me), I need to know what the two antennas are #1.

Next, what is the SWR of the antennas on the freqs that the tuner does not work for ant #2?

My use of LDG tuners, and it is certainly does not include older versions nor many models, but they do not need a reset. I have a wire loop that passes thru 2 trees. They give ample opportunity for varying VSWR which happens. Forgetting rain storms, but just a wet day in the summer versus a dry day in the summer causes automatic retune and my transceiver shows the resulting SWR which is not always the same low number .. but as long as it is low enough that my amp can handle, I don't care. If I did, I would have the LDG, MFJ, and Palstar ... wouldn't be a great review if some entity did a auto-tuner performance show down (I digress).

The antennas at home are an off center fed dipole and I only need the tuner for it on 80 meters where the swr is 2.5:1 where I operate and an end fed 88' wire that is fed with a 4:1 unun and the swr is only 3.5:1. The main antenna is the ocfd. Who knows what I'll be using out in the field when the weather gets better. With all this finicky operation, I'll most likely just use one of my manual tuners !

Well, I have tried that - it will retune by holding the tune button for more than one second, but on the next transmission it will retune to what is stored in memory. Once it does the memory tune, I can change to the antenna the memory tune was for and I've got a match, but the new antenna will only match when I do a full tune, to get a match for the new antenna I have to do a full tune on every transmission. Kind of flaky if you ask me. If they would only incorporate a reset button to where you could clear all memories it wouldn't be a problem. And if I used the same antenna all the time it really wouldn't matter. But I bought this tuner to use at home and in the field where I don't always use the same antenna, and once it stores settings for a particular antenna and frequency combination it wants to use that setting every time no matter what antenna I'm using ! If no reset is possible, is there a way to disable the memory tune feature ?

They don't provide a schematic in the manual Ed, and I haven't really tried to mess with the circuitry. Only thing I've done inside was to add a battery holder which amounted to soldering 2 wires. It has what I want to call a plug in eprom and I would figure that's where its all stored.

The tuner memory is stored in the CPU's internal non-volatile memory so there is nothing you can do in hardware to erase previous settings. As others have noted, the tuner will adapt to your changing antennas though automatically. Earlier LDG tuners did provide a method to clear the internal stored settings but that was removed in later models. The reason I heard, was that this feature was causing many service calls and confusion among users so the decision was made to rely on the more than adequate automatic adaptation of saving new settings that overwrite the older ones.

I wonder if the tuners program is in the same chip? It shouldn't be but bad news if so. Wipe the tuner memories and program at the same time. Perhaps you could reverse engineer the board to get an idea of the circuit but that would take time. Too bad LDG isn't being more helpful in this.

Actually LDG is being helpful through me since I wrote the core code that all of the tuners are based on since the AT-100. I have specific permission to help within my availability as a representative of LDG even though I'm not an employee at this time.

In all of the tuners for easily eight or more years, yes the program itself and the tuner memory settings are in the same chip and steps were taken so the program could not be erased accidentally so as to "brick" the tuner while tune settings are stored via locking critical program sectors. The CPU has the "fuse" setting where no one can read it to extract the program or tune settings but yes the chip could be erased and reprogrammed by LDG or maybe LDG could just send out a new chip, hence making the tuner like new, with no memorized settings.

Some of the earlier tuners had a separate serial EEPROM (typically an 8 pin DIP) that held the tuner settings externally but that dates back pretty far.

As I previously noted, the tuner is designed to "learn" continuously as the antenna load changes whether through weather, damage, rotation or even a change to a different antenna. When changing to a completely different antenna I would expect more full tunes (identical behavior to a blank chip) and then when frequencies are revisited the quick memory tune will once again dominate.

Maybe the best takeaway from this is that a new chip with blank tuner settings will always have to full tune as there are no memorized settings, just like if one changed to a new or different antenna. There will be little difference in observed behavior.

I mentioned on a previous thread that a full tune can sometimes happen very quickly even with no or few relay clicks as the tuner algorithm exits once the SWR threshold is met. An example here is if one took a new, no memorized setting, tuner and connected to a good dummy load and tuned on a variety of frequencies from a bypassed condition. The tuner would see 1:1 SWR and not proceed with the full tune. This is a QRM reducer and also provides for a faster tune most of the time.

Thank you very much for your input. It all helps for better
understanding of the tuners. I know I enjoy using my 600Pro and it's
very fast tuning capability... especially the ability to fine tune it by
manually increasing or decreasing capacitance and inductance to reduce
the SWR to a flat 1:1 if wanted.

Went back and read the whole thread. I was focused on the "why didn't LDG add a memory reset".

Try this....

Even if auto mode is turned off, try lowering the auto tune SWR threshold level to the lowest level. Page 18 of the user manual. See if this helps and report back.

I'm also curious what the old memory tune on the new antenna final SWR settles at. Is this value within the Spec of the tuner?

You know, come to think of it, I don't think the semi-auto mode is not working right. I have it set to semi-auto so it won't retune unless I tell it to. But, after making it tune, it still retunes to the memory settings on the second transmission - something isn't working quite right !

I have an obvious question, but the answer to the question is not obvious to me.

If I scan through say 3 frequencies i.e. 20, 30, and 40 meters, will the auto tuner tune as it scans through them?

If not, then how do you handle scanning when your antenna is not resonant through the scanned frequencies?

Thanks in advance.

The tuner needs RF to tune. So it will not tune as you listen to the various frequencies. The lack of tuning is no problem while receiving. So when you do transmit it will tune. That means everything should work just fine.

You are absolutely correct, the tuner equally affects transmit and receive. Going to bypass is the proper compromise, especially when changing bands.

That is certainly true. A non-resonant antenna makes for quiet listening. :)

The tuner needs RF to tune. So it will not tune as you listen to the various frequencies. The lack of tuning is no problem while receiving. So when you do transmit it will tune. That means everything should work just fine.

Bill KQ4YA

I have an obvious question, but the answer to the question is not obvious to me.

If I scan through say 3 frequencies i.e. 20, 30, and 40 meters, will the auto tuner tune as it scans through them?

If not, then how do you handle scanning when your antenna is not resonant through the scanned frequencies?

Thanks in advance.

If you are scanning in receive mode only, it would be best to just put the tuner in bypass. You are correct that it, like almost all external tuners, requires transmitting to tune or recall a previous memorized tune setting.

Put tuner in bypass while scanning so you don't get the preseclector effect from the tuner. When you transmit the tuner will do its thing and tune up.

The lack of tuning is no problem while receiving. <snip>

Unless the signal you want to hear is so weak it gets lost in the noise - an unturned antenna will not receive at maximum efficiency !

There should be no need for a fight.

Turn your receiver to a different band, do your auto tune, and notice that when you return to receive, the noise level and any signals are higher. If the match on the new band was pretty close with what you started with it might not be dramatic, but it will be noticeable.

Many antenna tuner manuals suggest starting by switching or turning your inductor for highest noise level then adjusting the capacitors to minimum SWR, until you arrive at an acceptable tune.

I see this with the RT-100, an AH-4 and the KAT100 autotuners, and the manual ones as well.

7817. Re: Scanning

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-03-31 02:29:45 UTC
From: jwalden@...
Topic: 7808 Message: 7817

In summary, the auto tuner is working as designed. It only auto tunes with a transmitted signal of sufficient strength. There is no information from the rx as to what frequency is being tuned to. When the rx is near the tx freq, the auto tuner as a filter provides a better match to the antenna and improves the signal to noise ... the desired received signal has a greater margin above the noise floor.

If your antenna(s) are well matched to the ham bands, there will be no such improvement. And, the expense of an autotuner was a waste. If your antenna (as mine) is put up in limited space and only sometimes is a good match at the operating freq, then an autotuner buys a lot more useable bandwidth. It is a necessity.

I don't yet have a reason to scan frequencies in a band much less across bands, but expect that I will soon enough. This discussion has given me thought that the band with the worse VSWR and/or with worse propagation conditions might be the one to have the favored preselection, pre-tuned to that band in other words with a blip from the tx. Controlling that auto-magically would be a trick ... perhaps a scrip in HRD?

In other words, the auto tuner does reduce the signal to noise (the noise floor seems higher) when not near the tuned frequency with a similar VSWR. By how much completely depends on your antenna VSWR.

I am not well versed on what different transceivers can provide, but it looks like there is room in the market place where the transceiver has the frequency memory for external auto tuners or some means that the rcvr tells the autotuner what (previously saved) frequency is to be tuned. Otherwise, as AD7AS said, put it into bypass and take what you can get.

Many antenna tuner manuals suggest starting by switching or turning your inductor for highest noise level then adjusting the capacitors to minimum SWR, until you arrive at an acceptable tune.<snip>

The difference is real easy to see with a manual tuner. Tune up on another band to assure its not tuned where you want to listen, then change to the frequency you do want to listen on and start changing the inductance and you will hear the signal levels change with it. Moving farter away from resonance the signals will drop, but as you get closer the signals will increase. I was a shortwave listener long before I got a ham license and built a few simple L match tuners to use with my wire antennas. Being receive only, all I could do was listen for a signal increase and tune for that. Now, many years later as a ham, I still tune that way first with a manual tuner, and then just touch it up with a short transmission to get spot on.

My old AT-100 can be used in manual mode to perform SWL duty as described out of the ham bands. It is located conveniently close to the receiver and easily within reach and the speaker is nearby. More of a problem is the remotely installed RT-100 with no manual mode available nor an easy bypass. I suppose something like a pair of old Dow coaxial relays could be wired into the system to bypass or connect the remote tuner and provide a similar function in the station for a tuner located there.

For clarification, I do not use the AT-100 ad RT-100 in the same feed simultaneously. Also manually tuning the AT-100 is very seldom done, for manual I use an even older Dentron! Someday I really have to thin the collection of devices.

Thanks for all of the food for thought.

I like the idea of taking the tuner out while scanning.

There were some other interesting suggestions such as tuning in the frequency where your antenna was the least resonant. I will have to play around some day, and see what I come up with that idea.

It helps to know for sure that the tuner is set to the the last tune that I set it to when scanning or I can put it in bypass.

One thing did confuse me. (I have a YT-100) ----- Several people seemed to say that I only needed to
transmit to get it to tune again. I certainly did not get that out of the manual. I thought that on the YT-100
I had to hold down the button until the red light came on and then release it, in order for the tuner to find a close memory tune. If I am wrong I am going to have to look at that manual again. It doesn't seem to be clear on that point.

7834. AT-1000ProII SWR Discrepancy???

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-04-30 14:43:24 UTC
From: RSLAUFER@...
Topic: 7834 Message: 7834

Riddle me this...

While on 10 meters, my AT-1000ProII appears to have auto-tuned tuning to a SWR of 1.1. Unfortunately, my radio (a Flex 6700) reports a SWR of 1.7, as does my SPE 1.3K-FA. My SPE 1.3K-FA repeatedly is warning me that my SWR is a bit too high.

By tapping on the manual controls I can bring down the SWR to 1.3 as reported on all devices (including the AT-1000ProII).

I have only noticed this odd behavior on 10 Meters.

I have the AT-1000ProII set to auto-tune at its lowest trigger SWR of 1.7.

Other than send it back to the factory, any ideas? Thoughts? Suggestions?

If it could do a "hard reset" I would try it, but it is my understanding that it can't do this.

Thanks!

Using a Z817 and its associated interface cable with an FT817ND, and the tuner doesn't follow the band settings. I can do a full tune on 80-10 with good results. I have to initiate a full tune tune when ever I change bands. Is this the way the z817 operates, or am I missing something? I thought the tuner remembered the settings for each band. Any info would be appreciated.

The tuner remembers settings for multiple places in each band. If I remember correctly, you have to transmit a carrier for a moment after you change bands. If that Freq +/- some kHz was used before, the tuner will recall the previous setting.

Since this can be a battery powered tuner, it does not keep in constant communication with the radio or the batteries would not last. The tuner detects a transmit, measures the frequency, and then will recall a previous match, if one was saved within a reasonable close proximity to the detected Freq. It even stores more than one last known good setting per Freq slot and will try all. If none of those result in an acceptable SWR, a full tune is started.

I hope the above helps.

Craig

Thanks Craig. I tried it that way, doing the full tune from 80 to 10, then dropped band by band, same freq as tuned on the way up, steady cxr for 5 seconds or so, and it still required a manual initiation on each band. Hmm. Have to try the tuner on another FT 817.

Can you connect the 817 to a computer and have it read out the frequency
and mode (like N1MM, or N3FJP logging programs?)

That would verify that the 817 is sending freq sigs to the tuner with
the same type cable. IF not it could be the cable or something set in
the 817 (or a defect in the firmware for the 817)>

Thank you Hank. No, can't connect to a comp. I'm going to try another FT817 later. If it acts the same way, may be a bad cable. When I find a schematic, I'll try checking it pin-to-pin.

The other thing to check is that you changed the FT817 settings menu per the LDG user manual.

I can initiate a full re-tune on a frequency by holding tune until the outer LEDs blink, then the inner LEDs bling, then letting up on the tune button. Often, it will work only on the 2nd try, perhaps due to timing of button release.

I double checked the set-up, and both radios were done according to the LDG manual.
I tried it on another FT817, same results. When I use an Elecraft T-1, I hear relays buzz in the tuner when I change bands, but not with a z817. Don't know if that's a concern. To rule out a jack problem, can the interface cable be plugged into the "computer" port? I also see that the pads for both jacks have been resoldered and not cleaned up. Also found 3 other pads that were reworked. This z817 was purchased new.

The Elecraft requires an additional accessory to do a recall tune as you describe and the accessory requires a "Y cable" for CAT passthrough which the LDG does without any accessories.

I don't think you need to try the "computer port" on the LDG.

Pressing the Z817 tune button for a second on band changes is all that is required. If you just want to do SWL listening, put the Z817 in bypass prior and change bands all you want.

GM Craig. I do use the Elecraft cable. I was probably mistaken in how the z817 operated. I thought it remembered some parameters that would cause it to tune with a just a cxr, and not a cxr and pushing the tune button. The only advantage I see with the ldg cabling is that you press the "tune" button instead of keying and then "tune".
My other LDGs go into "auto tune" at the tap of the key, and don't require a full tune sequence.
Thank you all for the help.

Hi:

I have been using an LDG-1000 Pro II tuner with my Yaesu FT-DX3000 transceiver.
Works great, very happy.
I just bought an automatic Elecraft KPA-500 Amplifier. I want to understand tuning
the LDG now that an AMP will be in the mix.

I had previously wired up a tune cable (Before buying the AMP) so that when I push TUNE on the LDG tuner,
it sends a low signal to the AUX connector on my Yaesu transceiver, which then puts out a 10 watt carrier
for tuning the LDG.

Now, adding an amplifier to the mix, I have two questions;

A. I assume I need to also wire a low signal from the LDG tune button and send that to the amplifier INHIBIT aux pin (Pin 11 on the Elecraft KPA-500 amp AUX connector
is INHIBIT low), so that the amp does NOT send power into the tuner during a
TUNE cycle. Right? (I don't desire to ignite the expensive tuner :-))

B. What about sequencing and timing? If I have the same wire from the LDG TUNE output going into both the Yaesu 3000 (to request a 10 watt carrier for tuning), and also into the AMP
to inhibit TX, do I need a timing delay relay? Is there a huge risk that the Yaesu will send
out the 10 watt carrier faster than the AMP will go into INHIBIT mode, and thereby send too much power into the LDG tuner? Or will this all happen fast enough so as not to matter?

Thanks so much for helping me get it right the first time.

Hi, I have almost the same setup, just my auto tuner is a MFJ (1, 500 watt).
Well, you have to move the DJ-injection past the output of the amplifier (again I use the MFJ DC-injector, able of handling 1,000 Watt).
This is what I do, amplifier on STANDBY, press my home made tuning TUNE- button and the remote auto tuner will tune, after the antenna tuning, I put the amplifier on and again press the TUNR button to fine tune my amplifier, the antenna is already tuned.

I'm using WSPR, which hops from band-to-band Tx/Rx encoded weak signals for propagation testing WSJT Home Page http://physics.princeton.edu/pulsar/K1JT/wspr.html

The rig in question is a Yaesu FT-817ND, SignaLink USB and LDG Z-11 Pro II tuner. I have manually tuned at each frequency on each band to store the tune settings. As WSPR hops band-to-band, it does a quick 2 second tune-up at the frequency, but the LDG doesn't jump to the stored settings and often give high SWR values. There is probably some drift as the FT-817ND heats/cools. Just how close to the memory frequency does the frequency chosen have to be to recall the stored settings?

UPDATE !

While on vacation a couple of weeks back I had a little time to play with the tuner some. What I found that was after doing a tune from memory which I have never got a super good match - around 1.7:1 at best and then sometimes it would retune on a second transmission to a higher level. Then sometimes had to go through a memory tune 2 or 3 times to get it to settle into a good match for the antenna being used at the time, indicated by the green LED alone. With a meter inline with the green LED on, it would sometimes show near a 2:1 on the meter and the other LED's would flash when transmitting but the meter stayed on whatever the initial setting was. But when the other LED's were flashing is when it was most likely to try to retune. So I found out that after it stopped tuning, it would stay set only after I did a manual tune to get the tuner to where it had a near perfect match as indicated on the external meter. After the manual tune, the other LED's did not flash and the tuner did not retune. So I'm thinking there may need to be some sort of adjustment needed on the SWR circuit in the tuner so it tunes to a better match when doing an auto tune. The tuner is capable of getting a super good match but always stops on something worse. This is confirmed by watching the external meter and seeing it go to a near perfect match several times before settling on a not so good match ! So, is there any adjustments that could better calibrate the SWR circuit in the tuner that anyone knows of ?

<snip>

No, you are quite wrong there my friend ! The purpose of the meter is to measure the load match and the tuner and the antenna are part of the load as a system. Why do you think they put the swr bridge in the tuner on the input side of the tuner ? Same with an external swr meter, it goes between the tuner and the radio. Igf you put it between the tuner and the antenna, the swr would not change unless you actually change the length of the antenna. To see what the tuner is doing it must go between the radio and the tuner.

KK2DOG that is not correct, the OP has his meter inline in the correct position between the transceiver and the tuner on his feed line. If you put the meter last in-line before the antenna like you are suggesting you are bypassing the tuner in the circuit, therefore the tuner will have no effect on the meters SWR reading. The tuner doesn't physically tune the antenna it simply fools for want of a better description the transceiver into seeing a near perfect match.

It really depends what you want to measure; the effectiveness of the tuner in reducing SWR, or the standing wave ratio on the coax after the tuner. Besides, it's not uncommon for an SWR meter between a rig and a tuner to disagree with the tuners LEDs, and this can be caused by the default tuner settings – I notice this thread mentions an SWR somewhere around 1.7 to 1 after tuning and it's possible the tuner is set to begin tuning only for an SWR of 2 to 1 or worse.

It depends on the information you want. A tuner is a matching device and will change its output impedance to match the condition of the antenna. The radio on the other hand expects a stable load. With a manual tuner the object is to transfer the greatest amount of RF while keeping the input impedance consistent. A tuner will not improve the SWR on the antenna, just make the radio happy. My old tube KWM-2 did not need a tuner since the output circuit was wide enough to match.

If an auto tuner functions properly there really isn't a great need for an SWR bridge since the tuner will present the radio with a constant impedance and match the antenna condition as best it can.

2:1 SWR is a return of 12%, not a biggie in my mind but I know hams that try to squeeze ever watt to the point of obsession.

Placing a meter on the antenna side will show antenna condition, not perfectly accurately as the real impedance of the antenna is obviously not that of the radio and the meter or we wouldn't be using a tuner. But consider that the tuner may cover a condition that is not obvious without measuring SWR on the actual antenna.

I have an AT-100ProII with my FT897 and it mostly works well but on ALE takes a notion to retune at inopportune times. My IC9100 has a tuner built in and honestly it is better, silent and fast.

I've worked airborne HF and radios that had to deal with pilots rapid transition in frequencies and the tuners had to keep up. A tuner is a tool

Subject: Re: [LDG-auto-tuners] Re: LDG tuners need to have a reset feature

KK2DOG that is not correct, the OP has his meter inline in the correct position between the transceiver and the tuner on his feed line. If you put the meter last in-line before the antenna like you are suggesting you are bypassing the tuner in the circuit, therefore the tuner will have no effect on the meters SWR reading. The tuner doesn't physically tune the antenna it simply fools for want of a better description the transceiver into seeing a near perfect match.'s

It should be Radio-Amplifier-Meter-Tuner. That's how my station is set up. That way you can see the VSWR that the amplifier is seeing.

Personally I'd like to have one before and after the tuner.
It allows you see see if there are any major changes to the antenna side as well as final power out. Between the transmitter and tuner to make sure it is matching properly. Without both you do not get a more complete picture..

KK2DOG I think that you may be confusing an SWR meter with an RF power meter?

The way you describe your line up is perfect to measure the power output from your transceiver / amp, but it will only measure the true VSWR reading from your antenna. It will not change VSWR readings when you tune the antenna with the tuner because you have the meter on the output side of the tuner when you actually want to measure the tuned VSWR reading that your tuner presents to your transceiver / amp on the input side of the tuner.

Your SWR meter is designed and calibrated for use at 50 Ohms. Your antenna impedance which the LDG
tuner is attempting to match could be anything from a few Ohms to several k Ohms. With the meter
between the tuner and antenna, Watt / SWR readings will be meaningless.

Actually, the tuner doesn't fool the radio. The tuner transforms the impedance of the antenna system to the 50 ohms that the radio requires by canceling out inductive and capacitive reactance by adding inductance and capacitance as needed.

We are not trying to measure output power, we are trying to measure the "tuned VSWR", so the meter "MUST" go between the tuner and the radio. In fact, if its the type of meter that will measure both swr and power, it will still measure you amp's output in that position too. In fact, you would want to measure the power going into the tuner to assure you are not exceeding the tuner's input limit !

I will give a schematic as best I can of the flow chart of my setup. It is imperative you have the SWR meter between the rig and the tuner:

FT-950 --> SB-200 --> SWR/Watt Meter --> LDG AT-600ProII --> Balun --> Antenna, center fed Flattop.

If you have the SWR meter between the tuner and antenna, the SWR will not change, but will show the antenna as having a bad SWR. It is the tuner that changes what the transmitter "sees", which is why some say a tuner is "just a foolin' yer transmitter", which it is definitely not; it is transforming impedance and reactance to the 50Ω non-reactive the transmitter needs in order to work. Therefore, if you put the SWR meter between the tuner and the rig, the meter will show what the transmitter "sees", which, if the tuner is doing its job, will be a low SWR.

Now, true, some antennas are just rotten radiators to begin with, and a tuner is just going to allow you to transmit into a rotten antenna. However, if you have an antenna like a flattop (at least 1/2 wave at the lowest frequency of operation, balanced wire fed to a balun near the tuner) which is low loss, it will radiate well, and I have worked over 105 countries with it, and not even half trying. Now, if you are trying to load up a 20 meter dipole on 80 meters, your tuner may tune it, but you will be losing over 90% of your power in line losses and tuner losses.

Meter needs to be between amp and tuner. You are measuring the true output of amp then. With yours, you are measuring the output through the meter, which can show some loss due to the tuner itself.

<KK2DOG I think that you may be confusing an SWR meter with an RF power meter? >
Let me try to clarify. I have my Palstar PM2000A watt/SWR meter at the end of the chain so that I can see what my antenna is doing, and to measure my total output power. I keep the radio's meter on the SWR setting so that I can see what the radio sees as well. When I hit the TUNE button on my LDG AT-1000PRO Autotuner, I keep an eye on the RADIO'S SWR meter for the lowest possible match, and watch for output on the Palstar. I've been doing this for quite awhaile now with no issues or adverse effects.

To measure your amplifier output the meter goes directly after the amplifier. The amplifier is just part of the radio system, just as the tuner is part of the antenna system.Time to read the ARRL handbook

This setup would give you an accurate output power reading if you were connected to a 50 ohm antenna. Someone else pointed this out that a wattmeter/VSWR meter is only accurate at it's design impedance, typically 50 ohms.

For an example, if you are using an all-band antenna and are trying to match a 3:1VSWR down to 1:1, the power readings that you see at the location you use (between tuner and antenna) are probably irrelevant. If you were to move the wattmeter 10 to 20 feet down the coax you would most likely get a different power reading. It's even possible to see a higher power reading than the amplifier is capable of developing due to meter inaccuracy.

Joe

Just put the meter where you like to read what ever information you are looking for. If you are really concerned, run 2 meters, one before and 1 after the tuner.

Of course, you could just build antennas that don't require tuners. You'll find (for the most part--yes, there are exceptions), the just work better.

There is no right or wrong. It is personal preference.

Depends on how the SWR meter is designed. Some will work quite good over a very large impedance range (like a bolometer on a directional coupler)..But $$$.

What he said. The concept of "fooling the radio" is just a sort of mysterious "black box" idea, sort of a magical thing, that can make the radio "see" something that isn't. It is too easy an explanation, and used by people when they want to make tuners sound to be a bad idea. It is instructive to notice how many Hams have them, and how many of them are accomplished DX'ers.

Many Hams do not have the room to have an antenna for each band, and many like to utilize so called "all band" antennas, like the Carolina Windom, the G5RV, the old and venerable "flattop" (generally 100 to 130 feet long with center fed balanced line back to the tuner), various loops, or just a 130 foot wire strung out the window. All of these work quite well as radiators on most, if not all, of the Ham bands, and only need their impedance transformed. Enter the tuner.

An antenna might work quite well at a full wave length, or even at 3/8 wave, but its impedance will be something other than 50Ω. The tuner takes that complex impedance, adds capacitance and inductance to it, and transforms it into a 50Ω non-reactive load for the transmitter (as most modern transmitters require a 50Ω load).

Now, where problems come in is where a Ham makes an antenna for, say 40 meters, and feeds it with 50Ω coax, and uses a tuner to tune it from 80 through 10. With 100 feet of coax, you will be losing over 90% of your signal on 80 meters!. 20 won't fare too well either, and the only place you will get a decent signal will be 15 meters (go ahead, ask me why!) However, if you feed it with balanced "window line", to a balun, then to the tuner, things change. The window line is low loss, does not eat up power like coax, and though a high impedance line, can easily be transformed by a tuner (often using a 4:1 balun) to something the transmitter can use, and thus almost all of your power is going to the antenna, and the tuner transforms the complex impedance to 50Ω, and you are talking to Togo at 5x9. And, yes, I did, last week, through a monster pileup.

Station here:

FT-950 or IC7000 ---> SB-200 ---> Swr meter (not really needed, as my tuner has one, and so does the amp - I am just old school) ---> LDG AT-600Pro II ---> 4:1 balun ---> about 30 feet of balanced line ---> 102' center fed antenna (MFJ-1777 - I was in a hurry, or I would have made it myself).

With this, I can work most DX pileups without the amp. For those I cannot, I turn on the 200. I usually manage to get through.

As an aside, many older rigs, especially ones from between the World Wars, would tune into most anything - coax was rarely used. After WWII, many rigs had tank circuits on the finals that would tune most anything - no need for a SWR meter, just load and dip. Even some later SSB rigs had nice generous tank circuits, and would tune most anything. However, manufacturers started making rigs for a 50Ω load, as it was easier and cheaper, and old military coax was cheap and plentiful. Around then, EF Johnson started making the Matchbox, and the world was changed!

Your getting there Alex...

In the old days no one worried or even knew about SWR. It wasn't until WW2 that it became an issue and a quantity to be dealt with.

Two issues started the "problem" one was the advent of Coax and the other was TVI. Some years later SSB and the transistor added greatly to the problems.

In the old days Ham transmitters used tubes and mostly had pi networks in the output. This "filter" could transform the high impedance tube to the 600 ohm open wire transmission line with most any antenna hung on the far end. Sure when you tuned up too fast or talked too loud (half the output power was in the AM sidebands) you could arc-over the load capacitor (Made by removing 2/3s of the plates from a broadcast radio tuning capacitor and running 1KW AM on 15 meters) or blow the little parasitic coils made by winding 10 turns around a 2 watt resistor. No big loss and something you could repair before the contact was lost.

The big problem started with coax. now the loss went from 0.02dB/100 ft for open wire lines to 0.8dB/100 ft for coax. This is a one-way 10% loss which may be very tolerable, but you missed the point. It is a 10% loss for each time the energy has to pass through the coax. With a 4:1 SWR the antenna will only accept 1/2 of the energy available and reflects the other half back toward the transmitter, loosing 10%, where it is reflected without any more loss to travel back toward the antenna with another 10% loss and this 50 % that was rejected by the antenna in the first pass is now 40% and again half of it is reflected back toward the transmitter where it comes again to the antenna , now 10%. This goes on for a while. The total loss of the original 90% power that was presented to the antenna adds up to about 60% . You lost 30% due to the SWR. and it was "only" 4:1. With 10:1 SWR you lose say 80%. Not good. No bother in the open wire and tube days. The energy rattled around a while but it seemed to eventually get into the antenna.

The next issue to plague coax was TVI. Most old timers ran dipoles or at least balanced antennas. This worked great for open wire lines, but coax is not a balanced system. Connecting coax directly to a balanced system works, but it will generate considerable energy in the common mode that is traveling around on the outside of the coax and radiating like any good antenna. Lots of TVI. So folks "invented" the Balloon and several ways to feed a balanced antenna with an unbalanced transmission line. Problem solved.

Transistors are not tubes and they do not like having their voltages or currents doubled as happens with a 4:1 SWR. Tubes don't mind near as much and usually you will take out a tuning cap long before the tube notices anything (they don't care for quadrupling the power but remember that the reflected energy is totally reflected at the radio end of the SWR driven cycling and doesn't get to the tubes or transistors but the peak voltage or current does.). So solid state radios will only make power by design into a very limited mismatch (like 2:1). They have clever circuits to prevent making the power to begin with so their output transistors are protected. It no longer a simple thing repairing a blown solid state final, but several hundred dollars and several weeks of down time. Guess why we most all have tuners??? It is easier to tune down the SWR than to tune up the antenna. BUT you are

still loosing all that power to SWR. Back to open wire lines!!

There is another solution. That is to have the tuner not in the shack next to your radio but on the tower next to the antenna. This is happening and is a great solution. Now you can use coax (tolerating the 10% power loss) and still get a 1:1 SWR for the radio. Weather-proof, automatic remote powered and actuated tuners are available from LDG or like I do I put my little Z-11ProII in a weatherproof box and it sits on my tower. I have a pair of 18650 LiIon cells that handle the tuner tuning and they were charged last year and are still going.

Subject: Re: [LDG-auto-tuners] Re: LDG tuners need to have a reset feature

What he said. The concept of "fooling the radio" is just a sort of mysterious "black box" idea, sort of a magical thing, that can make the radio "see" something that isn't. It is too easy an explanation, and used by people when they want to make tuners sound to be a bad idea. It is instructive to notice how many Hams have them, and how many of them are accomplished DX'ers.

Many Hams do not have the room to have an antenna for each band, and many like to utilize so called "all band" antennas, like the Carolina Windom, the G5RV, the old and venerable "flattop" (generally 100 to 130 feet long with center fed balanced line back to the tuner), various loops, or just a 130 foot wire strung out the window. All of these work quite well as radiators on most, if not all, of the Ham bands, and only need their impedance transformed. Enter the tuner.

An antenna might work quite well at a full wave length, or even at 3/8 wave, but its impedance will be something other than 50Ω. The tuner takes that complex impedance, adds capacitance and inductance to it, and transforms it into a 50Ω non-reactive load for the transmitter (as most modern transmitters require a 50Ω load).

Now, where problems come in is where a Ham makes an antenna for, say 40 meters, and feeds it with 50Ω coax, and uses a tuner to tune it from 80 through 10. With 100 feet of coax, you will be losing over 90% of your signal on 80 meters!. 20 won't fare too well either, and the only place you will get a decent signal will be 15 meters (go ahead, ask me why!) However, if you feed it with balanced "window line", to a balun, then to the tuner, things change. The window line is low loss, does not eat up power like coax, and though a high impedance line, can easily be transformed by a tuner (often using a 4:1 balun) to something the transmitter can use, and thus almost all of your power is going to the antenna, and the tuner transforms the complex impedance to 50Ω, and you are talking to Togo at 5x9. And, yes, I did, last week, through a monster pileup.

Station here:

FT-950 or IC7000 ---> SB-200 ---> Swr meter (not really needed, as my tuner has one, and so does the amp - I am just old school) ---> LDG AT-600Pro II ---> 4:1 balun ---> about 30 feet of balanced line ---> 102' center fed antenna (MFJ-1777 - I was in a hurry, or I would have made it myself).

With this, I can work most DX pileups without the amp. For those I cannot, I turn on the 200. I usually manage to get through.

As an aside, many older rigs, especially ones from between the World Wars, would tune into most anything - coax was rarely used. After WWII, many rigs had tank circuits on the finals that would tune most anything - no need for a SWR meter, just load and dip. Even some later SSB rigs had nice generous tank circuits, and would tune most anything. However, manufacturers started making rigs for a 50Ω load, as it was easier and cheaper, and old military coax was cheap and plentiful. Around then, EF Johnson started making the Matchbox, and the world was changed!

The tuner doesn't physically tune the antenna it simply fools for want of a better description the transceiver into seeing a near perfect match.'s <snip.

Actually, the tuner doesn't fool the radio. The tuner transforms the impedance of the antenna system to the 50 ohms that the radio requires by canceling out inductive and capacitive reactance by adding inductance and capacitance as needed.

7880. LDG could use a method of recording a manual setting for a given frequency

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-05-12 22:45:17 UTC
From: RSLAUFER@...
Topic: 7880 Message: 7880

I have previously asked about a curious finding that at some frequencies my AT-1000RroII is very confused about the SWR and selects a less than optimum tuning combination .

I can manually reduce the 1.7 SWR down to 1.3, BUT I have no way to set this manual setting for later use. If I leave that frequency and go back to it, my LDG wants to stay at the 1.7 SWR that it erroneously thinks is best!

The latest MFJ autotuner has a feature to record a manual settting into its memory for future use.

It would be nice if LDG had such a feature.

I thought that is a capability on many LDG tuners. Did you cross check the user manual? Check page 18 on the below :-)

I have two newer chips for my LDG AT-200Pro. The new chips are a 200PM13 and a 200PEP12 The old ones are a 200M13 and 200F12. I don’t have any instruction so can someone tell me do I just switch the 12 with the 12 and the 13 with the 13? And can I replace the head chip without pulling the board out of the case?

Thanks

"tuner goes between tuner and radio" ? I think you meant to say meter goes between tuner and radio ? But anyway, putting the meter between the tuner and the antenna is pointless since it would not tell us if the tuner is doing its job or not. If my antenna is far enough off that I need to use a tuner in the first place, then it would be a moot point to measure the swr there - I want to see that the tuner is actually matching the system to the radio, so I "ALWAYS" put the meter between the radio and the tuner. If the tuner is working, then the meter will show a low swr, if it doesn't show a low swr, then the antenna is either out of the matching range of the tuner or the tuner has a problem that needs checked.

My LDG is supposed to be able to do that by once I get the manual tune to a bare minimum, then you push the function button and then the store button, but it doesn't seem to work on mine. Tried it several times in the last few days. Got it down to where the meter shows no swr with the manual buttons, then push the function and store buttons to store it in memory, and on the next tune command on that frequency its right back to a less than optimum swr. Its like the function and store buttons are not connected to anything !

Ever since my Novice days I have done as taught by the ARRL manuals, my Novice class, and my Elmer and have my PWR/SWR meter between transmitter and tuner. Notice that is where the transmitter itself places it's built in meter. However, today just for grins and giggles I placed my meter between the tuner and antenna as has been insisted upon by some.

Using my HB 135' Doublet (non-resonant ladderline and element) my results were as I expected. After tuning and using 10W I found: SWR 1:1, measured before the tuner, and reading infinite between tuner and antenna with my 10 watts reflected. Placing a meter, that has listed in it's specifications 50 ohms Input / Output impedance, in a location that "sees" ∞ infinite impedance would not desirable IMO.

Perhaps the person(s) with their meters placed after the tuner see a usable SWR figure, but I would think that that particular antenna / feedline system must already be near resonance when seen by the meter and in that case the tuner is not needed if the rig has a built-in auto-tuner and they want to have the SWR at or near 1:1. Again that's just my opinion so do what you think is right for your reading accuracy and the longevity of your gear.

I believe that the hams here are responding to this topic out of concern for you and the investment you've made in this wonderful hobby/service.

My AT-600 ProII has a limit of 750 watts; you sure you downloaded the correct manual?

CW is around 50% duty cycle, give or take - why would it be any different than SSB?

But Don is right - so many get exercised at the difference between 600 and 900 watts. NOBODY can tell you are running 600. That rare DX will answer your QSL swearing he heard 900. The difference between 600 and 1200 watts is 3dB. 3dB is not hearable to the normal human ear, and is not readable on an S-meter. The difference between 600 and 900 is about 1.5 dB, not detectable at all.

The LDG documentation is very unclear about this. At least on my AT-100ProII, manual memory store only works when no RF is being applied to the tuner. In other words: 1) key your rig; 2) manually adjust the LDG C and L buttons for best SWR; 3) unkey your rig; 4) press "Func"; 5) press "Tune (Store)". That works for me to store the last manual tuning of a frequency in memory.

Yup I agree it's pointless placing the SWR meter after the tuner. So for those that still want to do this for whatever reason they may have why not put the meter where it belongs between the rig (or amp if you have one) and the the tuner then simply switch the tuner to bypass to get the antenna (and feedline's) SWR reading.

Well, the AT600ProII manual I am looking at online says 700 watts maximum power input "at most."
The AT1000ProII manual says "Single Side Band 1000 watts, CW 750 watts, digital 500 watts" with a maximum power input of 1200 watts "at most."

Anyway, I'm not going to pay $450 for a tuner that will require me to use my $1400 amp at the power level of a $900 amp.
That doesn't really make sense to me.
I'll probably stick with manual tuners.

Thanks 73

I agree too.

It may be nice to see if power is coming out of the tuner, but the reading is probably irrelevant. If you are tuning an antenna that is far from a 1:1 VSWR the power meter is not going to be accurate. It will only give you and accurate power reading at 50 ohms impedance. I have seen a case of a meter showing a higher power reading than the amplifier was capable of. Moving the meter 10 feet down the coax changed the power reading. But, whatever makes someone happy......

I have seen a case of a meter showing a higher power reading than the amplifier was capable of. <snip>

While I've never owned or used an amp, I have seen the meter show more than what the rig was capable of but only when the swr was high. Running a 100 watt radio and adjusting a manual tuner with a dual meter movement, I have notice the power go well beyond 100 watts according to the meter when the swr was too high, but drops back down to 100 watts when there is a good match. I think this is caused by the reflected power combining for lack of a better term with the forward power which gives a false reading. So yes, the meter will only show an accurate reading when it is being used at its design impedance. And if you put it between the tuner and the antenna, the impedance could be anywhere from a few ohms to several thousand ohms, which does not make for an accurate reading on a meter designed for 50 ohms.

This error in SWR is true for low cost SWR meters that use diodes to sample the power which are really reading a voltage (and "peak" at that) and depend upon some impedance knowledge to get to represent power.. This is not true for sensors that actually measure power (bolometers etc).

The diodes are RF rectifiers necessary to drive a meter directly. The RF is sampled (aka directional coupler) with something like a loop http://www.repeater-builder.com/projects/bird-element-tour/bird-element-tour.html.

I Suppose that depends up what you consider a low cost SWR meter. Both my Bird and Telewave meters use diodes to sample the power and they both cost several hundred dollars. I would consider a bolometer, such as the HP power meter, an expensive laboratory grade piece of test equipment.

The only time I used a Hewitt Packard power meter to accurately read power was at Nextel where we were accurately measuring the QAM digital output of a transmitter. We had to use this type of equipment due to the complex signal of the Nextel transmitter. The power meter I used only read forward power, I don't know how you could read reverse power with a bolometer. You would need both forward and reverse power readings to calculate SWR.

I found that I can easily initiate tuning of my AT-600Pro with my TS-590S by simply assigning the rig's TX Tune to the PF B front panel button. When I press the PF B function button the 590 goes into 10W transmit, tunes and with another quick press, I'm done. Works great. Perhaps other Kenwood owner's can use this.

7909. Z11 Pro2 manul memory store does work !

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-05-31 13:09:27 UTC
From: rmckee1957@...
Topic: 7909 Message: 7909

Got some more time to play with the Z11 Pro2 this weekend and finally got the manual memory store to actually work. After doing a full tune and only getting down to a 1.7: swr, I did the manual tune to tweak it down to a 1.1:1 and then did the manual store function. Next memory tune it went right back to the 1.7:1 that it originally found, so I did the manual tune and then manual store function again. I actually had to do this about 6 or 7 times in a row before it finally took and then actually used those settings in a memory tune. So I went to the next band up, same routine - took 6 or 7 times to get it to lock on and actually use those settings. That was on 80 and 40 meters, then on to 30 meters and it took 2 times to get it to lock onto and use the manual store settings. On 20 it always tuned to a very low SWR, so I skipped that band and went to 17 meters where it took 3 tries to get it to store the manual settings and all the other bands took similar procedures. Don't know why I had to "convince" the tuner those were the settings I wanted it to use, but it sure was stubborn about it ! But at least for now when I hit the tune button, it does drop the swr to a very low value that my Icom 706 Mk2's foldback circuit is happy with and now allows full output as the 1.7:1 only allowed about 80% output. Not that I would really worry about the loss of 20 watts on my signal mind you, but if it caused the radio to decrease power, I do wonder about efficiency through the tuner.

As I mentioned on another post, the tuner probably has a differing opinion of SWR because of the different SWR bridge locations, the tuner's vs your Rig or meter. There also could be a difference in calibration.

In any case, I am glad you got it to work. The reason it took a lot of stores is because there are multiple memories for each frequency slot. LDG did this so as to accommodate for issues like a wet vs dry antenna or a rotating beam that may interact with surrounding conductive materials depending on the direction it is pointing. In most cases, more memories are better. Per the user manual, there are over 2,000 memories and they are referenced by an internal frequency counter when the radio is transmitting.

==========
Could be a calibration issue, but I check my meters calibration periodically using a 50 ohm dummy load that actually measures 50 ohms on my Simpson DMM. I have a couple of FWD/REF meters that I built but my favorite is actually a Radio Shack digital SWR/power meter that also reads 1:1 when connected to the 50 ohm load - not scientific by a long shot but the digital readout is handy since it has a fine resolution which displays suttle changes !

In any case, I am glad you got it to work. The reason it took a lot of stores is because there are multiple memories for each frequency slot. ==========
I kind of thought maybe that each frequency was storing several memory settings since it took that many tries to get it to actually use the settings I wanted it to use and the only time I've noticed a weather induced swr change was during ice and snow, rain doesn't seem to affect my antennas much. But allow me to ask a question. If the tuner is storing multiple settings for one frequency, shouldn't I be able to keep hitting the tune button until it arrives at the properly stored memory settings for that situation ? If so, it has never seemed to work that way because no matter how many times I push the tune button, it always seems to stop in the same place like its stored half a dozen memories of the same settings. But anyway, you are saying that since it took several tries to get it to store the settings I wanted was because I was filling up the memory slots or re-writing those slots with the info I wanted which does make sense.

I think I also need to look at the calibration of the foldback circuit on my Icom 706 too as it is really aggressive. It starts dropping power the very second the swr goes over 1.5:1 and at 1.7:1 its only doing about 80 watts. Most rigs I've had only started dropping power when the swr went above 2:1, but maybe the Icom is set that way for a reason I don't know about, it just seems too aggressive to me !

To answer your question, the tuner overwrites the oldest memory on store but checks all on recall for what the tuner's internal SWR bridge shows as the best match.

> I think I also need to look at the calibration of the foldback circuit on my Icom 706 too as it is really aggressive. It starts dropping power the very second the swr goes over 1.5:1 and at 1.7:1 its only doing about 80 watts. Most rigs I've had only started dropping power when the swr went above 2:1, but maybe the Icom is set that way for a reason I don't know about, it just seems too aggressive to me !

To answer your question, the tuner overwrites the oldest memory on store but checks all on recall for what the tuner's internal SWR bridge shows as the best match. <snip>

How many memory slots does it fill per frequency before it starts rewriting them ? And when doing a memory tune for that frequency, does it look for the best one stored or just take them in order they were stored ? In other words, say its got 6 memories stored for 3.823 mhz. Will it go to the best match for the moment or would I have to keep hitting the tune button to scroll through the stored settings until it gets a good match ? That's the way mine seems to work, because on some frequencies/bands it takes a few tries before it settles on a decent match even though I've used it on that frequency before.

Another thing I've noticed since I now have it storing good settings is that more than one problem has been solved !

1. It is now showing a near 1:1 match on both my external swr meter and the one built into the radio after doing a memory tune and the radio does full output.

2. After doing a memory tune, the swr no longer fluctuates as indicated before by the multiple LED flashes on the tuner, external swr meter, or the one built into the radio. Before I forced it tto store settings I wanted it to use, only the green LED would be illuminated during the low power tuneup (about 9 watts), but when modulating full power on SSB or CW, the swr would fluctuate on the both meters and also shown by all the LED's flashing along with the green one. But after getting it to store good settings as shown by the meters and the green LED, neither the meters or LED's fluctuate and it maintains a steady reading on power peaks.

3. I can now operate it with my off center fed dipole on frequencies where the swr is as high as 5:1 like 15 and 60 meters where the antenna is not designed to be used. In fact, on 60 meters it would time out before it could find a good match, but I could do a manual tune and now have it stored so tuneup is very quick on that band. On 15 meters it would settle on about a 2:1 on its own, but now through the manual tune and store I have it doing a 1.2:1.

The number of memories per frequency slot varies by tuner. I don't have the quick answer but four is the minimum. On a memory tune it will go through all or until a match is found that meets the SWR threshold setting in the tuner per page 18 of the user manual. It is imaginable that if some of the memories are very close, one could be found to be the best one time vs another.

I'm glad you're having success and yes it sounds like your radio has a very sensitive roll-back threshold. Maybe download the service manual of the radio and see if you can raise the threshold some. 2.0:1 or a bit higher would seem more reasonable to me. However I would follow whatever the service manual indicates.

7916. Memory Reset

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-06-02 05:28:00 UTC
From: ldgyahoo@...
Topic: 7916 Message: 7916

We've been over this many times. There is no rational for the ability to reset the tuner memories to a factory setting of zero. So unless you want us to change the memory settings to a fake reset like MFJ does to make people feel better for absolutely no reason, we're not going to make any changes.

As Craig has explained, the tuner does not need to reset the memory settings. The software takes care of that for you. On any tune, if the memory is not finding a correct match, the tuner does a full tune and then stores the new match in memory. It's always acting in the best interest of the user to find and store the best match.
Other than that, there are just a couple settings (peak/average, hi/lo power range, ect) that the user can change that are different from the factory settings. However, it's easy to change those settings at any time and has nothing to do with the tuner's performance.

So, for the last time, there is no reason to reset the tuner memories as the software takes care of that for you and better than you could do. In addition, you can bypass the software selected setting by requesting a full tune at any time and the tuner will ignore the saved match and find a new one.

Not much to go on so start with the simple.

Is the RC100 controller hooked to a 12 VDC source and is the red power light on?

Is the RC100 in line between the transceiver and the tuner?

Did you a apply a cw carrier from the transceiver to start the tuning process.

Does your radio show VSWR or do you have a an external SWR meter between the transceiver and the tuner that will indicate the amount of reflected power which should drop as the tuner does its thing?

If the above conditions are met it should tune but may take up to 20 seconds per frequency the first time around.

Your antenna is showing an SWR at a certain point in the feedline.

I think this is what is happening. When you remove the RC-100 and associated jumpers/cables, it is going to change the reading that you get because you are moving the location of the meter in the line.

I would try this:
Put the RC-100 back in line and place the RC-100 first directly at the output of the transmitter. Then place the RC-100 directly at the input of the RC-100. I would bet that you will get different readings, depending on the length of the jumper that you are using between the transmitter and the RC_100.

Then put a good 50 ohm dummy load on the output of the RC-100. When you do this I would bet that the pass-thru works fine.

I think the antenna that is non-resonant at certain frequencies is causing your strange readings.

From: ldgyahoo@...
Topic: 7924 Message: 7924

Hello All,

Just a short update for a few changes happening. The LDG web site was upgraded to show the AL-100 and Z-817H to be discontinued. There are a few dealers that may have these models for a short period.

The file section in this newsgroup was updated with folders for schematics and firmware for LDG products. We'll eventually have all products in those folders, but we will be starting with the oldest first. A lot of editing still has to be done to the schematics and there is testing to make sure we have the correct firmware files from over 20 years of tuner building. This won't happen overnight, but we hope to have it all done this year.

Lastly, we'll be introducing two new Yaesu interface cables this summer. The YT-PAC-1200 will work with any of our generic tuners (Z-100Plus, Z-11ProII, AT-100ProII, AT-200ProII, AT-600ProII and AT-1000ProII) and the FT-450, 950 and 1200 series and the YT-PAC-3000 for our generic tuners and the FT-3000 radios.

That's it for now,

Dwayne Kincaid

Hello,

I would like a tuner for a FT-857d.
I am thinking about YT100 and the Z100plus.
The possibility to power the Z100plus using extra internal batteries is a great functionality when portable operations
and it has very low power consumption.
I would like a tuner which control the transceiver to tune in low power.
Question:
Is the Z100plus connected to the transceiver using the jack-jack cable put the transceiver in low power when tuning ?

I have a Z-100 plus and I use the "tuner to Radio" interface cable the one I have is short I added a longer stereo cable with a 1/8 inch stereo socket on one end
and a 1/8 inch stereo plug on the other. all I have to do is push the "TUNE" button on the LDG Z-100+ the radio goes to AM 25 watts, the display on the radio does not change from USB/LSB to AM but the LEDS on the tuner show the lower power level. I like the battery option
as well when operating portable one less current pull from my radio's battery.
I also like being able use the tuner with my QRP equipment if I had a dedicated tuner I could only
use it with my FT-857D.

Topic: 7934 Message: 7935

There is no issue using FM to tune, just be mindful of the tune power limitations. Most, if not all, radios will transmit full power on FM and CW, whereas they transmit a lower (when not modulated) power when in the AM mode.

So if you typically have tuned using AM, the power from the radio may be higher in CW or FM mode and just make sure the power output is acceptable for tuning per the user manual.

7937. LDG Z11 Pro 2 excessive tuning after match

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-06-27 02:58:56 UTC
From: ku4pt@...
Topic: 7937 Message: 7937

I bought a Z11 Pro 2 and the matching cable about a week ago to use at field day with an Icom 706.

Played with it several days at the house using my OCF antenna and it seemed to work fine on 40 meters
Took it to field day and was operating mainly on 20 meters to an ocf antenna that is about 130 feet long. The antenna checked out very well with a MFJ antenna analyzer.

I would press the tune button on either it or the the 706 and it would find a match and the correct led would be on. When I started talking on ssb it would sometimes start autotuning on its own. Made it unusable. I did find if I pulled the power plug out after I did a manual tune it would stay locked in like it is suppose to.

I thought it may be possiable that one of the other 3 transmitters that were in the same area could be tripping it to another band when they started transmitting and the antenna was picking up enough signal to fool it. Got home and using another OCF antenna and it would do the same thing.

Anyone else notice this ?

You might want to change the auto tune threshold to a higher SWR which is described in the user manual. I think this will solve your problem.

Thanks much, That seems to have solved the problem back at the house anyway.

I don't know what LDG sets it at at the factory, but I had set it for the least amount of SWR. I reset it to the second lowest and transmitted on it a bit into several antennas and when it found a match it never retuned. By mistake I even loaded my triband beam up on 80 meters with the LDG and it found a match and never retuned.

I have been a ham for many years and got my first class radiotelophone license around 1973. Used many manual tuners, but the only other automatic tuner I have used was the one built into the Icom 746 pro and it never acted this way. Guess they set the thresh hold high enough to prevent excessive tuning.

I also set my 706 and LDG to several bands and used my Icom 746 pro on another wire antenna that is at right angles to the 706 antenna and about 15 feet below it. That did not seem to cause any problems. I had thoght that at field day the antennas being only about 100 feet apart or less might have caused the LDG to pick up enough signal on a band it was not tuned to cause a problem, but probably not from the tests I have ran.

Indeed LDG does call it "semi-automatic" mode (read the manual!) and I'm glad they have added features and threshold adjustments so that the user can customize the tuner's performance.

There is a learning curve with this tuner. For my internal tuner of the Icom 746 pro there did not seem to be the learning curve. It tuned and stayed tuned. The LDG did not seem to want to do that. I think I messed up when I read the manual and set the 'thresh hold' to the lowest value. Not sure what LDG had it set for .
I bought this tuner to take to Field day and only had it a few days to learn how to use it. I have a manual tuner that I had been using,but as a number of people would be using the station I wanted something that was fully automatic.
I think after setting the tuner for a higher retune SWR thanks to the help here it seems to find a spot and quits tuning.

Hello Philip

I have two LDG tuners and neither goes into bypass when I shut off my radios.
I doubt that the IT100 does.

one of my tuners has two antenna inputs the tuner stays connected to the last antenna
I used be it beam or dipole and the latching relays stay in their last state when I turn off
the radio.

An autotuner is designed to tune when it detects a mismatch. LDG's, I think, can be set to only tune when you press the "tune" button, but this rather defeats the purpose. A mismatch that goes unnoticed can, even on modern rigs, cause some very expensive smoke. The autotuner is supposed to stop that from happening. My 3 autotuners go through a tune cycle if I go to a frequency I haven't been on in a while. Plus, my antenna is a 102' center fed (balun at the tuner), and the trees can detune it. My AT-600 Pro II will get very fussy sometimes, but it usually gets there in a few seconds.

The other thing is to do as I was doing for a while; I had an old Heath SA-2040, and that thing (still have it) is a hoss. I recorded band segments and settings, and could roll the inductor and tweak the capacitors to get the best match on any band, just had to find it in my book first. It could take a minute or two to get my shack tuned on a DX station, sometimes longer, especially if I had to tune the SB-200. I was fairly happy til I was chasing DX one day and when I got back after tuning up, the DX was gone. After this happened a few times, I switched to the AT-600 Pro II. I have not gone back. Shoot 10 watts through it, let it tune (less than 10 seconds usually, often it just says "ker-klung!"), and I am there, ready to jostle with the big boys. I have a better than 90% success rate on pileups...

Thanks for the response Craig. The needle was not stuck and it appeared to be functioning properly because it moved on SWR. The problem was that none of the 3 buttons would work. The device was stuck at 600, Peak, SWR.

Notice I am using past tense because this morning, after power had been off all night, it began working correctly. So you were right about taking power off. I tried that several times yesterday but apparently I didn't have it off long enough. I'm glad I did the full scale calibration but I'll not check it again.

Topic: 7956 Message: 7956

At times my AT-1000 Pro-II will not turn on.
(The POWER button has no action.)

I can resolve this by removing the DC power momentarily, then re-applying the DC power feed to the DC input connector on the rear of the tuner. ALWAYS, after this DC power-feed interruption, the tuner will power on and operate as normal IN ALL WAYS, including power on and off.

What can I do do resolve this condition? It happens on a very unpredictable basis, but more probably after the tuner has been OFF for several hours. -Sometimes...

Yes, your situation is very different from mine, Ken!

Another had emailed me (Vince K7NA) who had the same issue as mine, but in his case, he had resolved the problem by employing a small 1.2 amp power supply. (Previously, he had powered his AT-1000 ProII from the same 35 amp supply that powered his radio and also with a small 13.8 volt, half-amp supply)

So, I am going to experiment by adjusting my power supply that feeds other items, such as my HF radios; -I have increased the voltage from the (preset/indicated) 13.8 to about 14.25 volts. -In other words, just enough for a change. I will see if this makes a change as time goes on.

Aside from the power supply selection/choice, is there a better fix?

Thank you Vince and Ken, and 73! Mike, K0JTA

Its a quality issue. Mine does the same thing. There should have been a needle stop or a capacitor to slow the return to zero.

Quality is not something found in much of the ham industry. Check out my bio page on qrz.com.

Hi have the option to buy an AT1000 second-hand for a pretty reasonable price, with assurances as to its condition, or an AT600 ProII brand new. Whatever I get will be used to load up a full wave 80m loop fed by twinlead back to a heavy-duty 4:1 balun with a 10' jumper of LMR400 back to the tuner. I will be using an Ameritron AH811 driven to about 500w.

So, which would be the better choice? The AT1000 without warranty but better power handling or the At600 with less power handling, but newer software and a 2 year warranty. They both cost within 20% of each other.

Any advice would be appreciated.
Regards
Gerry

That is a hard call to make. I would say to save up some more money and buy a new AT-1000ProII. It is always better off having greater reserve/capability than to walk on the edge. I don’t know what the AT-1000 can’t do that the AT-1000ProII does so maybe someone else can shed some light on if it makes much of a difference between the two versions.

If the fellow is local and you can try it out for a week or so and the price is less than the 600 I would go with the at1000.
My way of looking at used gear is think of what it would cost to get it repaired for a not too major of a breakdown. Then subtract that from the cost. For the tuner if the used 1000 was less than the new 600 I would go for the 1000. If more, I would go with the 600.
  Right now the 1000 pro 2 is about $ 130 to $ 140 more new than the new 600.
One other thing, how is your operating habits ? Are you on the air once a week, once a day, or once a month ? If almost every day, then go with the new equipment. If like me and not on very often or would not use the tuner very often, then used is probably ok. I have a tuner,but the bands I operate on the most I don't need to use it.

Hi... Not local, unfortunately. He's in the US and I am in Ireland. A new AT1000 ProII is more than 2x an AT600 ProII... they are nearly $1000, whereas the AT600 is about $650. I take your point though, the headroom would be comforting.
Depending on the repair, I could likely do it myself. Certainly if it was a fried relay or capacitor.
I think I will wait another few weeks before I make a decision.
Thanks
Gerry

Gerry,
IMO. For use with a loop you will need a tuner with a broader tuning range... a balanced tuner or something like the PalStar AT2K I am using on my HB 80M Doublet.

Neal, that is absolutely incorrect. The meter does have a rubber bumper stop and it is controlled by software, not a capacitor.

We're looking into the issue to see if it's shipping that causes the bumper to move and then causing the meter to stick. The number of people that have this issue is quite small, so we're not sure if it's a production issue.

If memory serves me, and it often slips these days, the power ratings on LDG tuners is PEAK power.

If you plan on running a full 500W, I would opt for the 1000w unit and preferably a new one.

Folks at LDG are generally very good at standing by their products, and with a used unit, you don't have that same assurance.

Date: 2016-07-27 11:41:14 UTC
From: cbjesseeNH@...
Topic: 7976 Message: 7976

As per manual p12, I press TUNE once momentarily:
1. Left Green and Right RED LEDs light and Left GREEN goes out
2. All LEDs blink once

I press Tune again momentarily:
1. Same as above

I don't get the 3 blinks to indicate Bypass.

When I Long Press Tune for 2sec, outer LEDs light, Inner LEDs light, then far Right Tune LED blinks once. It happens on all bands. I cannot initiate manual tune.

What might I be missing?

Thanks, 73s,

Bret/KC1CJN

I have a Z-100 working very well, but today I found that it does not let pass RF when it tunes 10m even if the light ends green. Have not checked if it is a short or open circuit.

I guess I have a problem in a relay or coil, but any help will be appreciated.

If i bypass the tuner the RF goes out, so does in other bands.

I dont see any fault appart from that

Any sugestions

Regards EA1FC (I forgot my pass for the group)

I recently got an AT1000 ProII, which is replacing an MFJ 993b. They are different enough in behaviour that I am still a little apprehensive. I have noticed one behaviour that is not mentioned in the manual, or at least not where I could see it.

After a tuning cycle (on 17m, not that it matters) the bypass light lights up. No error condition flashes on the LED bars though. I am taking this to mean that the SWR on the feedline is sufficiently low as not to need tuning, as it shows about 1.7:1 bypassed. I can achieve a better match manually though.

Does this seem right?
Thanks
Gerry

I have never tried it, but when using a Johnson's Matchbox and later, a MFJ-949E, I did that with a 125 foot wire, which is about half wave for 80 meters. It worked OK, and received well. If you go to Radio Shack and get a standard "Banana plug", it will plug into the center of the SO-239 almost perfectly.

A note here: You better have a GOOD ground! Or a decent radial.

Hello,

I used a long wire on my LDG AT-897Plus.
The length was a quarter wave length for 40 m band hold by a pole of a 10m.
For the counterpoise , I added 10% to this length.

I could use it to all bands 40m to 6m with both a MFJ-16010 and the LDG AT-897Plus.

So you basically had a quarter wave 40 meter vertical with a slightly longer counterpoise wire. I'm not familiar with the AT-897Plus, but I would assume its similar in circuitry to the Z11 Pro 2. Thanks for the info.

I remoted one just inside the peak of the house where the coax enters the soffit vent. It worked fine. I did this because I was using a multiband antenna that had high VSWR on some bands. This cut down on the loss in the coax running through the house and reduced RF interference on electronics inside the house. It was inside the attic, so no need for waterproofing. I have a friend who uses them outdoors in a plastic food storage container with some success.

I have a friend that has several antennas located in a salt marsh behind his house. No matter what he has tried, the remote tuner still gets damage, even with desiccant in the waterproof box.

About the only way to avoid this would be to pressurize the box like commercial antenna systems do. It would be expensive, but you could run a piece of tubing out to the enclosure box and pressurize it with low pressure nitrogen. Way overkill, but the only way I can think of to absolutely protect the tuner.

You could try potting the boards in silicone or another suitable compound.
The YouTube will help you.

Some silicone is caustic and could damage components and solder connections - not a good thing ! I would say to build an enclosure of PVC pipe with one end sealed and the other with a screw on cap and install a metal tire valve in it so you could add some positive pressure to it. Of course the entrance for all cables would also need to be well sealed. It wouldn't take much pressure though, around 10 psi should do it and nitrogen would even be better.

About the only way to avoid this would be to pressurize the box like commercial antenna systems do. It would be expensive, but you could run a piece of tubing out to the enclosure box and pressurize it with low pressure nitrogen. Way overkill, but the only way I can think of to absolutely protect the tuner.

From: ldgyahoo@...
Topic: 7998 Message: 7998

Hello all,

We've uploaded the 68HC11 S19 firmware files for as many old products as we could find into the LDG Microprocessor Firmware folder here in this group. The format is product name (with no dashes), then the firmware version number (with no periods, _14_ would be V1.4), then the chip version (E2 or E9 for the 68HC11).

Those that can get the proper 68HC11 chips and can program them can now make replacement processors for many of our discontinued products.

Newer products use Microchip processors and eventually we'll be uploading the firmware for those units as well (discontinued units first).

I have the YT-100 for my FT-857D. I used it mobile for a long time but it stopped working and the status light just blinks. Anyone have any ideas how I can correct this. I really love this tuner. My radio is now my base radio for HF as well as VHF/UHF.

The antenna its connected to is a A-99 tuned for 10 Meters.

Thanks

KG6MXZ, 73

Dean

The last couple of months have been terrible here with my dad being hospitalized and then passed away last week and my equipment sitting around collecting dust. So to take my mind off things, I decided to try to work a little HF over the weekend. I connect my antenna, turn on the rig and hit the tune button and get a good match right away and start calling to see if the gang is around. I see the bar graph display jumping on voice peaks on the Icom 706Mk2 and thought I had it on power output mode but then noticed it was set to display swr. So I start checking ground wires, coax jumpers and other connections to see if I could find something loose and every thing seems good. I check the swr with a steady cw carrier and all shows fine but that is with only 10 watts. Go back to SSB and start calling and the swr is all over the place again but I notice the tuner isn't actually tuning - the swr is just fluctuating. So as a process of elimination, I disconnect the Z11 Pro2 and put the MFJ-949D in its place and tune up and start calling and the swr is rock solid. So I pull the cover off the Z11 to see if there is any evidence of arching with nothing obvious showing. Reconnect it with the top off so I can watch it while transmitting with the lights down low so I could see any flashes and none noted and even looked to see if there was anything loose in the tuner and everything looked solid. I'm really puzzled by this, so does anyone have any ideas ?

Sounds like RF is getting into the tuner and not in a good way.

Do you have any chokes on your feedline just before the tuner (looking back from the antenna?)

It could also be on the DC line into the tuner.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } Is it possible that the rig has a spurious oscillation? If you talk into the mic on SSB, does it continue to put out RF, like a carrier, until you unkey?

Rick,

I am using a LDG-RT-600 with the RC-600 remote control. I started having a noise issue while receiving.

I reached over to the RC-600 to try to tune it again and I noticed when I moved the actual control unit itself the noise went away. So I positioned the control unit so the PL-259s were resting on the SWR meter and the noise level was gone. If I moved the control unit the noise came back. So I put it back with the PL-259 resting on the SWR meter and the noise was gone again.

I mentioned the whole incident to a bunch of guys on a local net and one of the guys, who is just about everybody's elmer said he had a similar problem with a LDG tuner. After he took it apart and finally used a micrometer on the inner connector of the SO-239 he discovered it was out of spec and there was no way to make the hole smaller (The connectors were made in China).

I then emailed LDG explained the problem and after a days worth of emails they told me to send the RC-600 back and they would replace it. I had also notice the SWR (while in voice mode) changing as well.

I do not know if that is your problem or not but it is another thing to check.

I hope this helps.

73, Bill, KB1VGS, grid FN31xn

I've got RF chokes (three FT140-43 cores staked and 11 turn of RG58 through them) between the antenna feedline and the tuner. Got ferrite chokes on the control cable between radio and tuner and another choke in the jumper between the radio and tuner. It didn't do this the last time I used it and it was the same setup all the way - nothing has been changed. I checked the rig and there is no carrier on SSB, don't have a scope so I used another receiver to see if I could hear any spurs on other harmonics with none noted. I did find out that it does the same on CW and AM and even tried it with another rig - a Yaesu FT-840 and it still does the same thing, so it must be something common to the tuner itself. I'm thinking maybe a relay not making good contact or something like that, so I tried it on several bands so that different relays would be in use but it still does the same thing. I'm just beginning to believe its not meant for me to use an autotuner !

I did notice that while transmitting the other indicator LED's flash as I talk and that's after it shows only the green LED when finds a match at low power. So until I figure this out, I will be using my manual tuner but that will be after I get some on the air reports to see if there is any distortion while using the Z11 Pro 2, and also try it by allowing it to tune and then disconnect the DC power to see if it does the same thing. Will keep you guys posted.

I think that if you let it tune under a steady carrier,then unplug the 12 Volt power the swr will stay low. if so , check your settings. I had one doing the same thing and found that I needed to change a few settings. One was the minimum swr before it retunes and not sure what the others were right now.

8006. Anyone able to program a 68HC11 for a Z11 QRP?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-09-30 21:21:18 UTC
From: rentwist@...
Topic: 8006 Message: 8006

Hi,

Just joined the group. I recently bought a Z11 QRP for a song and fixed it up. It has some older (the original) firmware in the processor, 1.3 as I recall. Dwayne was kind enough to tell me about this group and about the files section. There is a version 1.6 with 200 memories in the folder (the original FW has no memories). So what I would like to do is get the current processor reprogrammed (or buy a new chip and program it). Anyone in the group have the ability? Think it is a 52 pin PLCC but will verify. Certainly not worth the trouble to buy HW specifically to program a processor this old but maybe someone in the group has the HW in their lab to do so?

Thanks and 73,

Robert, WA2T

Had a little more time this weekend to play with the tuner, and tried disconnecting the power after it tunes and it still does the same thing. The swr dances all over the place when operating full power (100 watts) but is rock steady when the rig is in tune mode which is 10 watts and the rig is an Icom 706 Mk2. So I tried my Icom AH-4 tuner and my SGC-237 and once tuned, both of those are rock steady. The swr doesn't go super high when talking on the LDG, but it does peak around 4:1 or so and shows about 1.2:1 in tune mode with 10 watts. So I'm thinking maybe one of the caps may have a problem. I pulled the cover off the tuner and looked at the caps real close and none of them look as if they've been overheated or anything like that, and watched the tuner circuit for arching while transmitting with none noticed. At this point I'm dumbfounded as to what is going on as it has only sat for a few weeks with very little operation and the last time it was used it was fine and then this crops up all of a sudden. So for now I'm using my manual tuner where there is no change no matter what power level I run. I don't think its meant for me to run an autotuner !

Rick:

Once the LDG has tuned, what SWR do you get if you transmit at very low power -- just enough to get a good SWR reading.

My guess is that you do in fact have a problem with the tuner (obviously since the other ones seem to work, unless you were using the other tuners with different antennas than the LDG was connected to). It's not uncommon for failures to be power sensitive.

As before, the radio tunes at 10 watts and shows a good match - about 1.2:1 into a Off Center Fed Dipole. I even disconnected the radio and checked the match both through the tuner which shows a good match with the analyzer, and then checked the antenna itself and nothing has changed there - its about 2.4:1 without the tuner at the same frequency and yes, its all on the same antenna. Tonight I'm going to let it make its match and reduce power all the way which would be about 5 watts and then increase power a little at a time to see at what pwr level the problem accurs.

Had a little time to check out the situation again last night and the problem starts getting noticeable around 35 to 40 watts, and 30 watts and under it seems to be ok. So I'm assuming that something is arching somewhere in the tuner but its just not arching in a place where I can see it. The tuner has always been operated with the interface cable with the Icom 706 Mk2 supplying the power, never more than 100 watts and most times less than that, and the only thing different is that it sat idle a lot while my dad was in the hospital and I didn't have a lot of time to operate. Antennas were always disconnected and grounded when not being used and everything checks out with the antenna the same as it was before per my notes when I built the antenna. Someone mentioned RF getting into the tuner, but I'm thinking how could that be in a device that is designed to operate with RF running through it and why did it start all of a sudden ? Oh, and I also checked that the center pins on the antenna connectors were fitting as tight as they could and made sure the SO-239's were tight - I have seen those loose on equipment before, even the ones that are riveted in.

Puzzled,
Rick, kc8aon

Rick:

Well, it sure sounds like a bad component or trace. I suppose it still be RF getting into the control circuitry of the tuner, but I think you said you put chokes all over it.

This could be a bad trace or carbon path somewhere, bad solder connection, bad component, or bad relay, so it might take some testing to sort it out. Starting out you might get lucky with a very close examination of everything. You are, however, making progress.

Yep, something in the tuner for sure - finding it is the problem. Bad thing is, this tuner has seen very little use in the time I've had it and problems crop up after it has been sitting idle without even being powered up for a few weeks. At this point I'm surely not sold on the auto tuner thing anymore and ready to go back to manual tuners that are slow but do work and don't require a DC source. I bought it because its an L network which is supposed to be much more efficient than the average T match manual tuners on the market, so I'm thinking maybe I just need to build myself a manual L match tuner and be done with the whole thing. It just bugs the life out of me to have new equipment sitting around that doesn't work properly !

I think I'll got to Harbor Freight this weekend and buy me one of those infrared thermometers and see if I can detect anything heating up in the tuner while transmitting. These thermometers have a laser aiming device on them, so I will transmit through the tuner and then check each tuning cap to see if any are hotter than the others. I think the thermometer is around $9.95 or so. Any thoughts ?

Adding to the pyrometer (love that term although HF devices might be a stretch), while at low power just below the tripping point, try heating up components locally with a hair dryer. Alternatively, if you can find a can of freeze spray, run the power up until it just starts have issues and try cooling down.

Rethinking the whole thing with cooler weather approaching, do you have a way of lowering the room temperature substantially?

Try one of these first that don't cost anything before you get a new toy. New toys are fun tho.

If the caps were shorted, I doubt it would be able to make a match to begin with. This one will make a match then goes haywire when you hit it with more power.

Is it possible that you have RF getting back into the shack? I have noted all kinds of similar reactions from equipments in my shack when either some antenna has a very high common-mode or I neglect to raise the tower at high power. (TH34XA 22 ft away at 1.5KW).

The tuner reacts to RF, and will automagically tune when RF goes through it. Many rigs, even modern ones (I have a FT-950) do not connect directly to the LDG. I tune mine (AT-600 ProII) by putting the rig on AM, pressing PTT until the rattling stops, and then going back to SSB. My AT-100 ProII is connected to my IC-700 on the other hand, and I just press the "Tune" button on the tuner, or the "TUNER/CALL" button on the 7000.

Just hook it to the rig with a coax jumper, connect it to a 12v power supply (WATCH THE POLARITY!!!) and just start operating.

Remember that at 100 watts, the voltages and/or current can be very high. It is recommended to tune with 10 watts carrier. I have no idea how much the tuner can stand while tuning, I just like to err on the side of caution.

Hi thank you for the reply, and the info. The Corsair 560 does not have AM mode it's a SSB/CW rig but I noticed that there is a spot on the mode switch called locked I'm just not sure if that is the same as a tx button like found on the more modern rigs. When I get my rig it should be in a week I'll check it out..

That is used to set the maximum power output using the external circuit breaker supplied with the Corsair. One turns it up until just below the point at which the breaker drops out, and this protects the rig's finals.

I highly recommend reading the manual! I also recommend obtaining the proper circuit breaker, but I can't tell you the source at my computer upstairs. Someone on the list will be able to do so, I'm sure.

While it's not meant to provide a tuning signal, you can certainly use it to reduce the CW output to a much lower power level for tuning; just remember to turn it up again afterwards – just not too far!

Hi All,

We got the FT-891 in and it's somewhat different as the 991. It' does not have a dedicated CAT port, so you cannot use the LDG YT-1200 with it. However, it does have a Rem port that can be used as the ACC port like in the FT-857 and 897. This allows users to use any Generic LDG tuner and the Y-ACC cable to closely integrate the two units.

The Y-ACC cable (for about $12 or you can make your own), will key the radio once the tuner button is pressed on the tuner and keep it keyed while the tuner is tuning. We did check and the radio also lowers the RF output power when tuning.

For the 891, you will need to set menu item 16-15 to Lamp (for Linear Amp). This would be the same operation if you used the Y-ACC cable with a Generic LDG tuner and plugged into the Rem port on the FT-991 and set menu 143 to the same setting.

New to the group. I put up my compromised 80 meter antenna yesterday. It is a Vee from FD but, due to lack of room, it is configured as a horizontal Vee apex in a tree at 35ft so I expected problems. MFJ 259C shows resonance at 3.5 at the end of 25ft of RG8X.

Connected it to Ant 1 and SWR was all over the place. Before I went out to "cut and try" I switched the 80 mtr antenna to Ant 2 (default) at all is well. What am I looking at here? Can't understand why switching between SO 239s would make a difference like that. How do I make Ant 1 behave itself?

Good day;

I had an issue with an LDG AT-1000 Pro-II: It would "hunt" after tune on 20 meters, if my feed line (window line) was wet. It progressed to this same HUNT when the weather was fine. It progressed to this same problem-indication when I was on 75 meters.

Previously, I had loosened, then tightened the PL-259 coax connector. One day, I happened to fully REMOVE the PL-259, and found that the male portion of the PL-259 had virtually NO CONTACT PRESSURE with the mate, the SO-239! Using a sharp tool, I "massaged" the four wipers of the SO-239 connector on the LDG tuner; -I now had contact pressure! I was again able to achieve a tune condition on all bands, including the troublesome 20 meters.

The previously discovered trouble has not returned in what is now over a year, and the tuner is not only STABLE, but it seems to be able to achieve a tune condition easier than before.

My point: Do check the contact pressure on the tuner's coax fittings as well as substituting the coax jumper cables, which is another source of troubles.

I've been waiting to see if anyone else had this problem. About a year ago, I had an AT600 ProII tuner that had bad SO-239 connectors. I measured the spacing of the center pin and found it to be out of specifications. I replaced the connectors with Amphenol Sp-239 connectors and all is well. The original SO-239 connectors were marked with "China".

I then sent the connectors back to LDG with a note explaining what I found. I also sent an email. They returned the connectors with no comment about the bad connectors.

Interestingly I have had a fault on mine but only on 80 metres with my AT600 PROII. I have not investigated it. I just put it to one side and left it. Maybe now I should get it out and get to work on it. This is a new one to replace an old one that I had that seemed to be faulty. I think I should get it out again and get to work n it. I am now using the ATU in the FT1200 and that works just fine.

Another quick fix here and one that I have used many times over the years is when I have a loose center pin, I squeeze the pin on the PL-259 with pliers to make it slightly oval which makes it fit tighter in the SO-239 socket. You can also build it up a little with silver bearing solder on the outside to make it thicker. Just don't know why so many manufacturers scrimp on something as trivial as a coax connector !

I have this radio with the LDG Z-100 V2.3 Z-LINE tuner board. LDG did an chip replacement upgrade to V2.8 that is installed in this unit. The tuner is giving me random operation including variable SWR indications. LDG no longer supports this tuner with no diagrams available. The first place I would like to start is relay testing and replacement, starting mainly with the unit transfer relay which may be identified as K8. There are 15 relays and are all labeled FRT3-SL2 9V with 2 Latching coils. In searching all I can find with this number is for 12V coils. This relay may still pull in at 9V, but may be unreliable. Wonder if if anyone in the group has source info on diagrams or a relay replacement. Thanks Jim

It may be scrimping or it may be the metric to American conversion.
I don't recall the details ,but MFJ was making some antenna tuners and the threads on the so-239 would not fit very well with the American pl259s. I don't think they were really using cheep connectors but just some mechanical conversion problems.

I have an AT-100ProII and would like to wonder why it says pro.

I just finished a military exercise with a number of countries on 44 frequencies. I cannot count the number of times the box found it necessary to go through a long retune cycle. Each channel was pretuned on two different antennas so should be in memory.

Using ALE the sounding cycle is not long and by the time the tuner figures out what to do, transmission stops.

I have another radio with a blistering fast tuner so the choice for next year is a T2FD or the bigger radio. This is not a good tuner for ALE since it cannot be easily forced into bypass during scan cycle. The last tuned channel is often a poor receive tune for the next channels. For the same reason it is poor for WSPR.

I'm surprised of the lack of variety of tuners with USB capabilities.

And don't use the excuse of RF feedback, its a tin box just full of RF and should be able to take 100 watts in a confined space. Stick your finger inside sometime to get a feeling of what is floating around.

Per the user manual, you should have tried raising the automatic tune initiation threshold. That most likely would have solved your problem.

I did, quite a while ago and it didn't make significant difference. Going past what it is set for now risks stressing my radio finals. For the heck of it I went up one more setting and half the channels in our training group retuned.

Most channels border ham bands but some are not at all harmonically related and the tuner has trouble with my 135' OCF.

Conclusion: Probably good for regular ham use, but inadequate for the ALE environment. Hear lots of grousing that the PC version was discontinued. There is a workaround to force the tuner into bypass but those I've talked to have not gotten it to work reliably. Setting bypass is only temporary, next channel change it drops out.

Pro: It has 6 meters which MFJ doesn't, and the watt meter is fairly consistent with my Bird.

I don't have the luxury (anymore) of having a squad of signalers building me field expedient antennas.

Well, my tuner is ready to be relegated to paper weight status. It's doing it weird thing again, get it tuned with low power and then when transmitting a full 100 watts the swr is dancing all over the place. But it's weird, the tuner isn't changing its settings - no relays switching or anything like that and even disconnected the power and the swr still changes on peaks. I even pulled the cover off and watched it with the lights off to see if I could see any arching with none noted. At this point I'm just putting it away so I don't even have to look at it, this is the third LDG tuner I've had with trouble from all 3 - time to move on and not look back.

The last couple of months have been terrible here with my dad being hospitalized and then passed away last week and my equipment sitting around collecting dust. So to take my mind off things, I decided to try to work a little HF over the weekend. I connect my antenna, turn on the rig and hit the tune button and get a good match right away and start calling to see if the gang is around. I see the bar graph display jumping on voice peaks on the Icom 706Mk2 and thought I had it on power output mode but then noticed it was set to display swr. So I start checking ground wires, coax jumpers and other connections to see if I could find something loose and every thing seems good. I check the swr with a steady cw carrier and all shows fine but that is with only 10 watts. Go back to SSB and start calling and the swr is all over the place again but I notice the tuner isn't actually tuning - the swr is just fluctuating. So as a process of elimination, I disconnect the Z11 Pro2 and put the MFJ-949D in its place and tune up and start calling and the swr is rock solid. So I pull the cover off the Z11 to see if there is any evidence of arching with nothing obvious showing. Reconnect it with the top off so I can watch it while transmitting with the lights down low so I could see any flashes and none noted and even looked to see if there was anything loose in the tuner and everything looked solid. I'm really puzzled by this, so does anyone have any ideas ?

Hi
I am running an RT600. I find that it does not remember prior setting and I have to do a full tune each time. I thought the relays were latching. All power is removed when I shut down.

Is there anyway to reverse the LC network?

Howie,

Some of the RT-600 manuals have a typo. The RT-600 does not have latching relays. The RT-100 does have latching relays. The latest manual is available on the LDG web site.

There is no way to reverse the L-C network. The tuner calculates that when tuning and I'm not sure how anyone would know which way to configure it if manual control was available. Many of our generic tuners have that feature, but we rarely (maybe never) hear of anyone using that.

Hi David,

I have the LDG AT 1000 Pro II which is similar to your tuner. The tuner derived its 11-15V DC from either the 706 OR from a wall wart that should have been provided with your tuner. There is a four conductor jumper that goes from the back of the 706 to the two jacks on the back of the tuner called "radio" and "power". That jumper allows the front "tune" button on the 706 to tune. If you want to use the tuner with the 706 powered down then supply the required voltage to the "power" jack and then you can tune the Collins with the tune button on the front of the tuner.

Hope this helps. OR, you can just power up the ICOM.

Are you using the IC-PAC interface cable? That cable is Icom specific. You would need to provide power to the back jack with a separate cable if using a non-icom transceiver.

Yes I am using the interface cable for the ICOM. I have a AT-200PROII and that worked fine between the two radios. Using the S-Line I did not have to turn on the ICOM to make it tune. I replaced a manual tuner with the AT-600PROII as I have a 30l1 that I like to use and the AT-200PROII does not handle anything over 200 watts. Just seems the AT-600PROII needs something from the ICOM to make it work when connected to the tuner via the interface cable. Oh I do have a separate 12VDC line connected to the tuner along with the interface cable.

Are you using the IC-PAC interface cable? That cable is Icom specific. You would need to provide power to the back jack with a separate cable if using a non-icom transceiver.

Thanks Ron. I do have a separate power cable from my power supply to the Tuner. I really would like to be able to have the AT-600PROII tune when using the Collins S-Line without having to turn on the ICOM. Now if I remove the ICOM cable the tuner will power on ok. With the ICOM interface cable connected and the ICOM turned off the tuner will not power on.

I'm going to have to look at the cable connector for the interface to see if it opens the DC path from the DC input cable when interface cable is plugged in. Only thing I can think of that would not allow the turner to power up when the interface cable is plugged in and the ICOM turned off. This didn't seem to be a problem with the AT-200PROII.

To use with the 706, it takes power off the 706 rear panel to run the tuner. If the 706 is not on, you will need a wire with a plug on it that goes to the concentric plug on the back panel of the tuner and supply it with 12v DC. I run an AT-100 ProII with my Icom 7000, plugged into the "tuner" 4 pin plug, but with my Yaesu 950, I use an AT-600 ProII, and have to have a plug with 12v. Look on the tuner back panel. Email me directly if you need more help. A 12v wall wart will work if the plug is right.

From: David Birnbaum
Topic: 8071 Message: 8071

I have an RT-100 which has been working fine. Recently I had to replace the pushbutton switch that controls the DC power. Unfortunately I picked up a normally open switch but when I push and hold the switch to tune the antenna the tuner works. When I release the button the antenna stays tuned. It's behaving as if the relays in the tuner were latching relays but I've been told that there are no latching relays. So while I'm waiting for my NC pushbutton to arrive can I leave the current setup and just power the tuner when I change bands?

If I'm correct, the RT-100 does have latching relays so a normally open pushbutton is the right choice so I wouldn't change anything.

The Tune button is normally closed and just interrupts the DC going to the tuner when it is pushed which will start a retune/memory cycle. The same functionality can be achieved by using the power switch. Once ON, the tuner should detect your band change so turning it on and off and back on should not be necessary unless you want to force a retune.

It sounds like you have replaced the TUNE switch which is Normally Closed. When Pushed it interrupts DC to the tuner and when released the tuner comes back on and will do a tune cycle. The same functionality can be had by using cycling the power with the power switch. That is the way it works for my RT-100.

I understand how the tuner normally works. But in my current setup there is normally no power to the tuner until I push the button. When I do so the tuner goes through a tune cycle. When I release the button the antenna stays tuned. That shouldn't happen if the RT-100 uses normal realys since when power goes off when I release the button the realys should all open up and the tuner is no longer properly configured to tune the antenna.

In the past I've been told the tuner does not use latching relays. If it does use latching relays that would explain the behavior I'm seeing. The only disadvantage of my current setup is that if I change frequency the tuner won't re-tune unless I force it by pushing the button.

I would think the tuner would need to be powered on to "tune" if you changed bands or frequencies. using the NO button and pushing the TUNE button would tune to your desired frequency.

can you just tune using the "tune" button without pushing the Power button.
I will have to see if my tuner, not an RT100 will work without powering it on.
I'm guessing it won't otherwise why would you need the power?

My RT100 doesn't do anything with the power off, but it does retain the last setting, whatever it was. With power on, it will tune if it needs to when it senses RF. I only operate CW QRP, probably in a restrictive range on each band, the lowest 50-60 kHz or so. I can't remember the last time I asked it to force a tune it didn't see the need to do.

The RT-100 uses latching relays so it will retain its last setting before shutting the power off.

When you say push the button, which button? The RC-100 controller has as a power and a tune button. Perhaps you are not using the RC-100.

Larry:

It is funny, but sometimes not funny. The glass jar thing is one of those. The amount of voltage that can be generated at the end of an un-terminated cable, in even just a nearby strike, can be substantial. It's not likely the class jar will do much to contain a discharge. The better thing is to terminate the cable to a ground point somewhere in your single-point ground window so that both the shield and the center conductor are grounded, OR, just leave it connected to the radio (which should also be in the single-point ground window with a protector on it somewhere). --- Just saying...

I really don't see this happening. By placing the end of the cable in a glass jar you would be setting up a very high resistance to ground for the energy. Where would the energy flow to after it entered the jar? The only possible thing is that the end of the connector was arcing over to itself. There are videos of this on YouTube showing the connector end arcing, but I don't see this as creating enough energy to blow up the jar.

A direct hit is going to take the path (or more correctly paths) of least resistance. I don't see going to a glass jar. Maybe someone else can explain how this may happen.

Glass jar being a good insulator, more charge building up before arc over, hot resulting higher net energy plasma arc from inside to outside the jar fractures it. I've heard some wild first hand stories of direct hits. With a direct hit, ground vs center conductor does not always behave as we may think.

Joe:

The thing to keep in mind is that we're dealing with potentially very high voltages and lots of current. A cable that's not terminated on one end but into which current can be induced can end up with an amazing amount of voltage at the free end. If it runs parallel to the strike or other conductors that have impulse current induced in them (either directly or by coupling to them) energy is induced into the cable with the free end being a voltage node. The coax insulation and the jar are not sufficient to prevent a discharge to something nearby, or perhaps even across the room. If that free end is instead terminated, it's no longer a high-voltage node, or at least everything associated with it is at the same voltage (single point ground concept).

Also, a hit taking the path of least resistance is a relative matter. Even if you assume that path is a low resistance, there's going to be lots of current and much of that is effectively at a high frequency. That make any conductor a voltage dropping resistor and also an inductor that has reactance.

These are the reasons that lots of things near a strike also get hit, although perhaps with less energy and often not from the main strike but from other induced current/voltage. The main point here is that this much energy is not easily contained, which is why you need to deal with it wisely. So, if you're going to disconnect a transmission line, the best thing to do is to throw it outside and well clear of the house!

Chuck - N8DNX

8091. AT-200PROII 'No-Tune'

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-12-27 20:30:47 UTC
From: va7mnm@...
Topic: 8091 Message: 8091

Hello, group.

I am having an issue with my AT-200PROII tuner and not sure yet if I need to send it in for repairs.

I have the AT-200 ProII tuner paired with an ICOM-7200.
Everything has been working fine for the past year, but then all of a sudden after working PSK31 it seemed as if some RFI was getting into the tuner. The tuner would re-tune part way into the transmission. Unhooked all cables to install snap on chokes, hooked it all back up again and now the tuner will not tune by the tuner button the IC-7200, and also not on the PROII.

When I hit 'tune' on the Pro2 I get the error message: ERR_NO_RF: Blink Once
I did a factory reset on the radio. Still the same.
Installed my original LDG IT-100 tuner to the radio. Works flawlessly.
Checked the interface cable for the PRO2 and all seems fine.
Ground connections on the tuner, radio etc. are solid and clean.
Does not appear to be my radio.

The function button on tuner and functions work fine.
Any suggestions would be very much appreciated.

Marc

Hi Marc

LDG has a user group on yahoo groups that you may find helpful, Dwayne the owner of ldg answers questions

Give LDG tech support folks a phone call,maybe you have overlooked something simple.

WONDERING IF THE TUNER PROCESSOR MIGHT BE CORUPTED if external rf meters confirmed rf is present at the input

Here is a quote from the product sheet did you exceed these power level on digital note the digital level is 50 watt

 It handles 100 watts SSB or 50 watts FM/Digital when used with a solid-state transceiver; vacuum tube transmitters cut the power ratings about in half.

Remember the tuner has a two year warranty

Have you confirmed the dc voltage level is proper between 11-16v to dc power input jack bad voltage waveform can mess up the meter electronics from a wall wart there likely to ask you about the producct yo use and the part number.

LDG will likely ask about the wall wart supply if your powering it via that input.

Have you confirmed with a cw signal thru use of a key that the error message of no rf is true read page16 for no rf description without using the tune button remember to manually set power at say 10 watt.if it tunes then the tune circuitry is suspect

Have you checked that the power output level is less than 25 w at TUNE have you put a rf wattmeter in line between the IC7200 TX output and tuner input so you have an external indication that rf does exist and this method does not rely on digital display power output of your IC 7200.

Hi, Doug.

Those are all good points to keep in mind.
I will print out your response if my unit goes out again.

It's funny, everything was working absolutely fine for a year, then it just started to act up.
I think I will invest in some more RF snap on chokes just to be sure.
Thanks for replying.

8096. RT-100 No Tune

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2016-12-30 22:49:44 UTC
From: larsonjim@...
Topic: 8096 Message: 8096

I've had my RT-100 with RC-100 controller for a little more than 2 years and has worked trouble free until very recently. It must have known that the warranty just expired!!

Now, it won't tune any more. It's stuck just below the 40 meter band. It won't tune to any band. Nothing happens when I press the tune button. I've also tried the other tricks that LDG recommends.

I measured the DC voltage after the injector. I get 13.5 VDC with the coax cable disconnected from the RT-100 and 12.5 VDC when it is connected. A 1 VDC drop through the injector seems like a lot.

The power supply voltage is stable with load. I'm using the Powerwerx SPS-30DM power supply which also power my TS-50. It's the same power supply that I've used the last 2 years.

Has anybody come across this before? It'd be really nice to have a schematic but none available.

Thanks
Jim AA4NP

Start with a dummy load. Are you getting dc voltage at the RT-100? Test the coax on both sides of the RT-100.

I would eliminate the coax from the RT-100 to the twin lead, run twin lead to the RT-100 with a Balun, and extend the 102' dipole to 132' or so. When I did this years ago, it made all the difference in the world. Of course this makes it an ordinary dipole, so you lose the magic of G5RVness.

Hello all,
I am new to this reflector.
I have an early Flex 5000a that has an LDG at-200pc tuner in it.
It searches for a second or so and can't find a match and the display says "high SWR"
When the tuner is in bypass mode there is continuity from the input to the output.
When it is in the ATU mode there is no continuity from the input to output.
I'm thinking that one of the relays must have a bad contact.
I am in need of a schematic and can't seem to find one.
I haven't yet emailed LDG to see if they could send me one.
Maybe someone here can help.
Thanks,
Don W9BHI

Dear Friends.

I´m user of a AT-7000 LDG tuner.

It works fine through last 5 years but last night went in fail.

When I push the Tuner button on the IC-7000 , tuner lights on the display
and go off inmediatelly. No action on the relays. I just push the reset
switch on the PC board and red light blinks as manual said. But no reaction
of the relays. All cable are ok. Perhaps a mistake in the conection sending
(by accident) power on the antenna output.

Have you some idea ? or schematics to follow the circuit ?

About a week ago I noticed a 30 over static noise on my wire antenna that I tune with the RT-100. I was able to stop the noise by turning the RC-100 off and on or just a quick tx of a few watts. Today the noise seems to be here to stay as long as power is applied to the RC-100 controller. If I push the Power button on the RC-100 and turn it off all is quiet. The tuner still works though. Anyone got an idea as to what the problem might be?

Thanks,
Larry

Hi Larry,

By the sound of it, the source is closer to your wire antenna. Lots of the wall warts are switch mode power supplies now. Could be something in your own shack. Phone chargers, even the one on your internet modem or router (don't forget some have a backup battery too so disconnect them too for the test), A short Tx may cause it to stop making noise, RF does some strance things to poorly build circuits.

Time to power the HF rig from a battery, hook just the antenna to the rig, Turn off one circuit at a time in the house till they are all off. I chased a noise like that for days till I did this procedure. Problem was a Vacuum Display alarm clock in my own house! Could even be the garage door opener or a heated reptile cage (another ham I know).

If this don't clear it, then next take an old CB walkie talkie and walk the neighborhood. When you get close, collapse the antenna and shield the radio with some tin foil, sweep till you find it.

Hopefully you don't have a small "grow operation" hiding in your neighborhood. Cheep import LED grow lights emit tons of crap. A microwave oven tears up my HF.

Good luck! Let us know what you find.

Hi Larry,

This is why I asked what you were powering your tuner with. Like the gentleman above states, wall warts can be a problem. When you say you powered down the station, did you only turn off the Astron? Or did you use a master switch to shut everything off? Maybe you power cycled something else if you have a master power switch for you station.

Joe

Hi Jim,

The noise is only heard when I power up the RC-100 Remote. It disappears when I turn it off. Only noise is through my receiver, nothing is heard on my signal when transmitting. I am sure it is related to the tuner and the tuner only. As I mentioned on two different occasions the noise can be stopped by turning the RC-100 off and on numerous times until it all of a sudden stops.

The tuner is power thru a bias T? All connections with it are clean ... and dry?

Another thing to check... Open up the outdoor unit and make sure there is no corrosion on the PCB. The tuner CPU should go to sleep if there is no transmit RF but if there is some corrosion, maybe the CPU is staying awake and causing the problem you are observing.

You might be hearing hash from the system computer or from some other source, but not likely the latter. Check grds and check conditions of caps. You might want to consider changing the wall wart power supply or if not one, then check the caps around the processor and the basic power distribution.

8118. FS: LDG YT-1200 autotuner for Yaesu radios

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-02-03 18:51:35 UTC
From: af5cc2@...
Topic: 8118 Message: 8118

I have for sale a LDG Electronics YT-1200 HF/6m autotuner in excellent condition. This tuner works with the FT-450, FT950, FTDX-1200, FTDX3000, FT991, and FT2000 radios, it might work with a few more also.

It loads up about anything. An included CAT/Power cable interfaces with your FT-450(D), FT991, FT950, FTDX-1200 and FTDX-3000. This makes it an integrated tuner powered by the interface. No extra power cables are needed. Just press the tune button on the tuner and everything else happens automatically! The mode is set to carrier and the RF power is reduced, a tune cycle runs and the radio is returned to the original settings.

They sell new for $233, I am asking $160 shipped. It comes with the manual, cables, and original box.

Hi,

I need some piece of advise, how to deal with an issue with my YT-1200 auto-tuner and LDG's customer support.

I purchased the auto-tuner and connected to my FTdx3000 transceiver as described in the manual provided with the purchase (making sure I absolutely follow all instructions, and of course double checking it several times). When tuning is initiated, it works sometimes, but most of the time, it powers down the transceiver, and then the transceiver restarts leaving the band in AM mode.

I contacted LDG's customer support early in December by email, as it seems the only way to contact them. I received no reply, however I was patient with them, since it was Christmas season, so I wrote another email sometime in mid January. This is Feb 8, and there is still no reply.

The YT-1200 manual contains a support email address, but it bounces. So far, what I was told at the eHam.net forum, is that never buy LDG tuners. I think this is the last LDG product I bought.

Thanks and 73,
Steve,
N9EU

I do not have a FTdx3000. I just came back in from removing at least 10" of snow and my arms are rubber. Therefore the only thing I feel like doing right is reading. You are the lucky one, I read your post about your tuner issue.

Because my fingers are the only part of me that can do much of anything, I looked up the manuals for your Yaesu & LDG. It appears to me, the interface is a cable that can only be plugged in at both ends only one way? Seems fool proof. However, I notice on page 9 of the YT-1200 manual the suggested grounding point. Two thoughts come to mind, 1) you are grounded? That means good RF grounding all the way to the Earth. 2) assuming, "of course", try testing the grounds and to only one location ... thinking about a potential ground loop.

1) is about corroded ground connection and RF electrically short ground runs
2) is what it says, grounds loops

I suggest this, given what sounds like a random-ish issue. Random-ish issues suggest RF and grounding interaction that can be difficult to track down.

My 2¢

Well...I assume you have the correct cable plugged into the back of the icom 718 into the tuner control port. And you have the other end plugged into the ldg tuner. What this does is two things...it powers the tuner, and when you press the tuner button on the front of the 718, it send a small amount of rf power to the tuner which in turn starts the antenna tuning process. If the tuner was successful, then your swr should be low. Another thing from the LDG website:

If you are using this cable with the IC-718, be sure to set the tuner menu to "4". The LDG tuner and interface cable emulates the Icom-AH-4 tuner.

Good Luck /73

With the tuner cable between the Icom 718 and the tuner, it not only powers the tuner, but allows you to initiate the tune cycle by pressing the tune button on the radio. In other words it makes it so the radio can control the tuner. I am running an Icom 7000 with an AT-200 Pro II and the interface cable.

I blew L4 toroid and ordered a 94-6 replacement toroid for a couple dollars. (kitsandparts.com).

The originals are all red, probably for looks only, since the operating range of red toroids doesn't cover the ham bands.

The 94-6 is yellow and is the proper range.

Hopefully I'll be able to get all the glue off and a replacement made.

Does anyone know the specific toroid number in case I was wrong.

If so, how much are replacements from LDG?

Wonder what a new processor chip would cost for an LDG Z-11Pro2 ? Would love to see if I could get mine to work properly !

Well, I did find the LDG emails in my Gmail spam folder. Something about the settings they use for sending email trigger it to get flagged.

I had several emails back and forth with the LDG guys and they are sending me a new processor chip to see if it resolves the problems.

The bottom line. If you have not gotten a reply to your emails, CHECK YOUR SPAM FOLDER. Most likely it is in there,

Wonder if a new chip would help my 600 Pro. worked for about a month, quit. Sent it to LDG, worked for about a week and quit again. Hopefully I can find someone here in Houston to work on it without a schematic. If I had waited a while to get the thing, I may have bought a Pro II. On social security now, no way to replace it.

As we've learned recently, LDG actually does answer emails, thanks to those who spent time to look through their spam folders and report back to us.

Maybe send LDG an email and ask your question along with noting the problems you're observing.

No this is not an official LDG support form. If you have a support question, you should contact LDG directly.

That said, yes sometimes you will see posts from LDG here.

Great, when we pay for things and they do not always work to snuff we gripe

which is nature. Dewayne might need to hire someone with his work load but
that takes profits away too. He is a fine fellow and I honestly believe he
does his durn best, no matter how well some things are made they are not

fixable, I am a 50 yr example of broadcast, tv, long distance and fiber
optic and wireless cell phone and it don't always go as planned.

8158. Z-11 QRP - Won't auto-tune

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-02-28 02:26:19 UTC
From: gibbsjj@...
Topic: 8158 Message: 8158

Greetings. I've just inherited a Z-11 QRP tuner with a W4RT one-touch tune setup. The tuner powers up fine, but will not tune. I've got it connected to an FT-817. I've tried it both in manual and auto modes. I've also tried with the 'one touch' connected and not connected. No change.

When I work the cap and ind switches I can hear clicking and it does have an affect on the SWR (as indicated by the SWR meter in the radio). It seems like the tuner isn't 'seeing' any RF going in (hence not trying to tune), but I've verified that the radio is putting out pretty close to 5 watts on high power. I've tried on a couple different bands and its the same behavior. I'm using a key and CW mode to generate the RF. The tuner just blinks its LEDs at me and never kicks off a tuning cycle.

I've opened up the case and everything inside looks clean and intact - no burned smells or any obvious damage.

Any thoughts? I did read the manual and I've used other auto tuners before... I don't think I'm doing something dumb, but ya never know =)

Thanks for any advice!

-Josh

Topic: 8158 Message: 8160

Hi Bob,

Thanks for the reply. This is what happens:

Turn unit on: all 4 LEDs blink once.

Antenna and radio connected to tuner, tuner switched to manual, radio tuned to 40 meters, CW mode (key connected), radio set to low power (1/2 watt, verified with a Bird watt meter). I hold down CW key to TX - radio indicates high SWR. I hold down the tune button on the Z-11 while transmitting - the left 3 LEDs blink (slightly faster than once per second). No clicking or other sounds from the tuner. The LEDs continue to blink as long as I keep the tune button pressed. I kept this up for 30 seconds. Same behavior in 'Auto' mode.

I can operate the cap and ind switches, and they work. I can hear clicking and if I adjust them far enough the noise level on the receiver starts going down.

Any thoughts?

Thanks!

-Josh

Didn't quite follow all that. Here's what I do. It may help.

I make sure the 7300 tuner icon is on. I set the rig to auto tune when the mike button is hit it automatically tunes. Of course I have the tuner/rig cable connected.

I have the at600pro and refer to the manual when things go wrong. I need to see if it has a 'master reset'.

I just finished the tough task of replacing one of the toroids I fried accidentally.

Good luck, Bo

Thanks for the replies guys. As stated in my first post, I already read the

manual, more than once. I'm certain there is something wrong with the
tuner. I was hoping someone in this group might have experienced the same
failure and have an idea of what the fix might be.

Bob: My radio is a Yaesu FT-817 - there is no tuner icon. I've tried the
reset - no change. Something in the tuner is broken, just not sure what.

Please, please forgive me for asking.You do have the radio going to the radio/transceiver connector and the antenna going to the antenna connector and not reversed correct?
It sounds like it is tuned to the 50ohm load of the radio and coax so it won't initiate a tuning sequence.
I am only asking because, well, let's just say that I heard of someone doing that before getting in a hurry to play radio. Hi hi

Hi Joe,

Yes, I have triple-checked that =)

Apparently this tuner was available as a kit, and some searching turned up the build instructions. I'm going to open it back up and try the calibration procedure mentioned in the build instructions. Will also have a look at the underside of the board.

Thanks for the help so far guys. If I have any luck I will post back here and let you know.

My IC-7300 controlled by the tuner sets output power to 10 watts. Try that.

Bob,

The tuner I have here is the LDG Z-11 QRP - it's marketed as a perfect tuner for the FT-817. This FT-817 only puts out 5 watts on high power. According to the manual, the tuner "requires only 0.1 watts to tune".

I'm still having a problem getting the tuner to remember a 4 MHz MARS frequency. The channel is manually tuned and after the radio has done an ALE channel cycle the next sounding on that frequency causes the tuner to retune. I have SWR thresholds set high, which I don't like but there is not much improvement.

Where is the SWR sensor, before of after the tuning circuit.

I ended up hooking the tuner up to my TS-450 so I could put a bit more power to it. Tried 10 watts - same behavior. The tuner acts like it doesn't sense any RF.

Wow, you've tried everything. Unfortunately a schematic isn't available.

I cooked a toroid in my 600pro and am doing repair myself. I can send you a photo of the RF input and the SWR/RF detecting circuit if you want to look for a simple fix internally. Bo

Interesting, I don't recall them in my two LDG manuals.
Anyway
The RF goes thru the center of a toroid, which has a winding, a 50 ohm resistor, and TWO BACK TO BACK SIGNAL DIODES (maybe 1N914 or germanium).

Bet that's it

Bo

Thanks Larry. I've got the schematic.

I got an email from LDG saying it sounds like the SWR diodes may be the problem, so I'm going to replace them and see if that does the trick. Appreciate the help.

The schematic is also in the files section for this Yahoo group. The schematic says they are 1N4148 but Dwayne @ LDG said they are 1N34A. I've got the QRP version, so that might account for the difference. Will see what is in there when I get home this evening and fire up the soldering iron!

Yes about a 300% difference. The 1N34A was used for better low power performance.

No it's not. I of course saw that but it tells me nothing. I tells me how to use the tuner but doesn't say what the cable (YT-PAC-1200) does. In other words, that description matches what the tuner does now without the cable.

Thanks for looking.

I'd like to think that the cable provides automatic power reduction during tune but the description doesn't indicate that capability.

Reporting back with a happy ending. I replaced the two diodes and it solved the problem. The diodes I removed were in fact 1N4148 like the schematic says, but I replaced them with 1N34A since that is what Dwayne said to use.

This Z-11 QRP lives to tune another day!

Glad I spotted it for you.

I too was successful in my 600pro repair!

A few bucks for a toroid, a LOT of work, and tech support from LDG and I replaced the cooked toroid.

I can't remember how I cooked it.

BTW the quality of the LDG tuner is impressive. As a retired engineer and long time ham, it's design is unique and impressive.

And you gotta love the popcorn machine audio.

Also if you hook it up backwards no harm is done!

I'm not sure but I know with my two tuners when I use the cables the power to the radio is reduced and the mode is switched on the
radio so the tuner has a carrier. Although the mode is not displayed
on the radio's display. I have two generic tuners so I need to push
the "tune" button on the tuner.
hope this helps because that's all I know.....

I thought I'd answered this.

The cables simply automate the tuning process IF you have a rig that issues the CI-V commands.

The 600 pro uses two cables, the newer ones do it with one cable with the IC7300.

On the 7300 you simply touch the mike button or change frequency a bunch.

If you don't like it's results you simply hold the tune button for a few seconds.

What else do you need to know?

Obviously if you are in SSB mode it has to change mode to either AM or CW to work. When I use this cable with my FT-450D and my AT-1000ProII my external wattmeter shows 100 watts when moving from band to band which have already been tuned and stored in memory. I switched to 160 meters, where my antenna is NOT resonant, and the power out varies from 5 to 100 watts while it is trying to tune so I think the radio is folding back due to mismatch as opposed to the tuner placing the radio into a fixed low output.

When I use this cable with my FT-450D and my AT-1000ProII my external wattmeter shows 100 watts when moving from band to band which have already been tuned and stored in memory. I switched to 160 meters, where my antenna is NOT resonant, and the power out varies from 5 to 100 watts while it is trying to tune so I think the radio is folding back due to mismatch as opposed to the tuner placing the radio into a fixed low output.

Brian I just checked my radio and tuner.
I'm using a generic LDG tuner which has the cable from the radio to the tuner.
I have to push the "tune" button on the tuner it switches modes but does NOT
reduce power. maybe LDG would be the one to ask.

You could tap into Fwd and Rev power at the test points that connect to the 1N34 diodes and use an Op-Amp (maybe 10k input impedance) to buffer and scale to drive a meter. However be aware that the meter scale will not be linear. The LDG meters are not driven directly but by the CPU which does a multi point scaling and calibration for each band.

I put up a rotatable dipole awhile back based on this article http://www.w5dxp.com/rotdip/rotdip.htm.

I used 6' telescoping aluminum tubing, a fiberglass tube center and fed it with 450 ohm twinlead. It was mounted at ~35' on a Rohn mast with an old AR22 rotator. I used an Icom AH-4 on the exterior wall of the shack for matching.

Performance was pretty good, but due to poor engineering of the feed line attaching scheme, the feedline fell off in a storm. Also, I realized that 44' of tubing is a lot for a small rotator to handle. It did, but barely.

If I were to do this again, I would use a couple of fiberglass poles with wire inside, like S9v31 verticals horizontal.

When I took it down, it was replaced with a horizontal loop.

8201. RT100+RC100 : is there a way ...

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-03-23 23:00:57 UTC
From: i2jjr-hotmail.com
Topic: 8201 Message: 8201

*Hallo Dwayne, and you all Readers.**
**I would like to know if there is a way to know when the remote tuner RT100 (or RT600) is doing a tuning procedure, in order to lower the output power of the rig to a level that better suit the specification of the tuner.

I have imagined **some easy solution to that problem;designed but not built, yet .

Suppose that you change frequency and the tuner suddenly does retune the antenna ... doing it at full power is not exactly what LDG suggest for them!
So I need some sort of signal back from the tuner that causes a reduced output from the rig; suppose i.e. instead of 100w CW to have 10w carrier .
If I let the RT100 do the tuning procedure at full 100W output, if I remember the specs, may give failures. Probably worse yet if I let the RT600 tune with full 500w applied ...
**
**When I use the Icom rigs with Icom AH-4 the tuning automatically reduces output to a safe value; I would like to do **the same **with Yaesu rigs and RT100 in one other location (and RT600 elsewhere)

****Somebody has experienced something like this with these LDG remote tuners? **
**Dwayne do you have some hint for me?

**** 73, es keep the good job,
Augusto I2JJR / HB9TZA
(soon 5R8JR)

**(I still wait the version of the RC100 - RC600 with incorporated cross-needle SWR-meter, as I told you some time ago ... May I hope? I have homebrewed something like that by now ...) *

8202. ICOM 707 with my LDG IT-100

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-03-24 17:08:21 UTC
From: kc8jwa@...
Topic: 8202 Message: 8202

Hello,
Does anyone else in the world out there still use a Icom 707 and used a LDG IT-100 with it?
I just purchased the tuner. The Icom is set to a AH-3 Tuner as it is suppose to be.

Before and after trying to tune the rig, the THRU is on which is suppose to mean that it is not tuning.
I am not familiar with this tuner.
Also, if the swr is good, does the green light stay on the tuner all the time or does it just flash for a moment.

Thanks for any help. It's hard because the 707 is not near as popular as some of the other rigs.

Bev

I will also put a photo or two in the photos section.

I have my answer and wanted to share in case anyone else in the future wonders the same.

Thank you,
Bev

8204. March LDG Update

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-03-26 22:01:06 UTC
From: ldgyahoo@...
Topic: 8204 Message: 8204

A couple of things this month. Some good news is we are now shipping the YT-1200 with a new firmware version V1.1. We had an issue with our firmware and the FT-991 radio about six months ago and had stopped shipping the units. With the V1.1 firmware, it now works with the FT-450, FT-450D, FT-950, FT-991, FT-991, FTdx-1200 and FTdx-3000.
While updating the firmware, we also added a feature that there are now no menu settings required for any of the compatible radios except FT-991 and FT-991A that now only has one menu setting. Users can select any baud rate and any RTS or TOT setting on any of the radios. It will also pass any baud rate.
This new version is a recommend upgrade for those that have the YT-1200 and wish to use it with a YT-991 or YT-991A. For all others, the upgrade is optional.
hose that purchased their YT-1200 between May 1, 2016 and March 31, 2017 are eligible to receive a free processor and manual by mailing a copy of their receipt to LDG.
For YT-450 owners, this processor and firmware is also compatible with the YT-450. This unique situation will update the YT-450 into a current YT-1200. Replacement V1.1 processors will be available from www.cheapham.com http://www.cheapham.com for about $20.

We’ve also discontinued two older interface cables. The AL-PAC for the Alinco SR8T and SR9T and the IC-2000 for Yaesu FT-2000.

That’s it for this month,

Dwayne Kincaid

Hi Jon,

That adds some complication, but e-mail should be fine as long as the receipt is completely readable and in pdf format.

Also, I forgot to mention how to find the version number. Users would take the lid off with the four screws on the sides of the chassis and look at the sticker that is on the processor.

8213. RT100 may be dead

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2017-04-13 18:37:46 UTC
From: Jim Allen
Topic: 8213 Message: 8213

The new RT100 put into service a few months ago appears to be inop. I have and use the matching RC100.

Perusing the manual, I don't see any suggested or preferred method of testing it for proper operation. I'd prefer to use a dummy load, stay off the air.

Does anyone have an idea how I can test this device? I suppose testing the RC100 for voltages is one of the first checks. I expect to hear relays moving, etc when it is doing the tune bit.

TIA

I just tune to a clear freq. It uses low power.
If your SWR is ok it does nothing.
Holding the button in a while makes it tune.

The lights tell the story. If it has power but plays dead you either have the cables backward like me or the signal diodes are shot and it's not detecting any power input.
Bo W4GHV since '54
Should be easy to TS. I fried a toroid and replaced it. Nice tuners.

8215. Re: RT100 may be dead

Yep. I'm insecure, I guess. When you talk about lights on yours, and I don't see any lights, I worry. Maybe I have it inside out or something. Maybe all the lights are out, and the party's over!

I set it all up with short jumpers, checked voltages, tried a couple of tune sequences and everything appeared to be just like the manufacturer's guarantee. It appears reports of its demise were greatly exaggerated. No telling why it did not seem to be functional in situ, but it wasn't the unit.

That's a relief! I experience periodic maintenance issues quite often, which seldom end in this benign fashion.

Hello Jerry,

As we have mentioned on here before, we have never found a reason for a microprocessor hard reset.

Can you elaborate on why you may need this? This could be a good group discussion.

I've said this before but will repeat it anyway. The reason I think they need a reset or at least a way to clear the memories is that sometimes we hams change antennas completely and would LOVE to be able to delete the memories from the old antenna to make the learning of the new settings and storing of those stings quicker.

Topic: 8231 Message: 8231

Hi,This is my second LGD 600 Pro. I purchased the first one in 2011 and it's done yeoman service. It still works perfectly. I purchased the 600 Pro II about a month ago or so along with the 600 meter in order to have a more accurate power out reading for digital modes.
This Pro II has an quirk. It will not set the SWR below 1.7. It cycles upward through the settings to 3.5, then goes back to 1.7. I've checked the manual and it seems as though it should cycle through 3.5 then go to 1.0 just as my 600 Pro does/did. Is this a defective unit or is this a common occurrence? Any way to reset it myself or does it need to be sent back to LDG? Thanks.
As a separate question, is it safe to assume the 600 meter power readings (watts) reflect the output from the tuner and not the input from the transceiver?
Thanks in advance for the help!
John/KC9TND

The SWR threshold should be adjustable. Perhaps you have it set to 1.7?

Hi Dwayne,
As a separate question, how did LDG decide to make 1.7 the lowest SWR threshold setting for auto-matching with the LDG 600 Pro II? I'm not questioning the decision, just curious. I would have thought 1.5 a more obvious choice though it probably puts more strain on the tuner.

Thanks,

John/KC9TND

Just like a cranky computer - when it isn't working right, reboot it and sometimes it will work fine ! Clear the memories to get rid of whatever is confusing the tuner and maybe it will work better. Mine doesn't seem to be learning new settings and most of the time it will not retain setting saved with the manual store function - its like all that does is to make the LED's flash, as on the next tuning cycle it goes back to the settings I did not store.

John

That's a great question. I don't think anyone has ever asked that before.

The main reason is that the specification of the tuner is such that if the SWR is less than 10 to 1, the tuner will reduce the SWR to 1.5 or less. So tuners with an auto mode can't have the setting any less than 1.7.

As some have mentioned, some of our earlier tuners allowed a setting lower than 1.7. That was great, but the user could create an infinite loop if the tuner was able to find a 1.5 and the Auto Start threshold was also set to 1.5. It would retune every time even though the SWR was good.

In the end, it was much less confusing to have the Auto Start threshold not be within the range of the specifications of the tuner.

Has anyone had any success using the meter connection to control the tuner? I'm trying to get it going...

I've bought a USB serial cable that has 5V TTL output, but I'm having trouble sourcing the 4 pin connector. So, temporarily, I stuck wires into the right holes and gave it a shot. No luck, no response from the tuner for any documented command.

With this cable I bought, I think there is no need to connect anything to the 12 volt output from the tuner, so I only connected rxd, txd, and ground. Is this right? Or, does the tuner need to see some kind of load on that 12v line in order to realize it's plugged in? If so, could I fool it by adding a resistor of the right value between the 12+ and ground? If so, what value for the resistor?

I triple checked the port settings - 38400, 8N1, no for control. I measured 5v on the TTL lines of the cable, too, and watched it drop on the txd line when I sent a bunch of characters over the port, so I'm pretty sure that part of it is working.

My intent is to eventually code an app for controlling the tuner. I'd also like to try to figure out how to get and decode meter readings so that my app could display them. This will help me while running remotely to make sure my amplifier and the tuner itself are online and doing their jobs. Unfortunately, the commands for reading the meters are not documented, so I hope LDG will fix that.

Thanks and 73,

Bill WK2X

Hello Dwayne,

I was disappointed in the fact that the LDG-600ProII would only tune to a VSWR of 1.7 to 1. I am using the tuner with an Ameritron ALS-600 amplifier at a remote site. At full output of 600 watts, the reflected power of a VSWR of 1.7 to 1 would be 40+ watts. The ALS-600 amplifier wants to see less than 50 watts of reflected power.

This is an excerpt from the ALS-600 amplifier manual:

"If the reflected power exceeds 50 watts the power level should be reduced until the reflected
power indicated on the internal meter is 50 watts or less on peaks. At approximately 75
watts of reflected power the internal safety circuitry will disable the amplifier."

This means that, with a VSWR of 1.7 to 1, I am getting close to a reflected power level that becomes questionable. It becomes more of a concern when the station is sometimes 1,000 miles away and I loose the ability to watch meters. My solution has been to add an Elecraft wattmeter to the station and remotely watch VSWR and power levels. Solid state amplifiers are less forgiving of VSWR than tube amplifiers.

I would like to see the tuner tune to 1.3 to 1 VSWR.

73, Joe, K1ike

Adding on to this. Older ft857 were known to already start fold back by 1.7. My newer ft950 with the internal tuner off is starting to show fold back at 1.7 so I have to agree with Joe on wanting 1.3 and threshold of 1.5 which the older 100 and 200 supported.

I completely agree with Mike on this. 1.7 is too high for a limit. If the tuner can't get a better match than that, then maybe it's time to fix the antenna it's trying to match.

With my full wave 80m loop, I frequently find that the running for one band, say 15m, will also appear to be "close enough" on 12m to be under 1.7, so the tuner won't auto-tune. However, if I manually force a memory or full tune, it can get it down to 1.1, and give a much more ideal match.

This is why I want to write my remote control app for the tuner - so I can force a full tune when it thinks 1.7 is good enough but I know it can do better.

I know my old Icom 706Mk2 starts folding back around 1.7:1 and is really aggressive at 2:1. Just recently bought a Yaesu FT-450AT and haven't noticed that on it yet but the tuner in it handles my homebrew Windom just fine where a tuner is needed.

Rick
KC8AON

---In LDG-auto-tuners@yahoogroups.com, <leonardpennock@...> wrote :

Adding on to this. Older ft857 were known to already start fold back by 1.7. My newer ft950 with the internal tuner off is starting to show fold back at 1.7 so I have to agree with Joe on wanting 1.3 and threshold of 1.5 which the older 100 and 200 supported.

On April 27, 2017 3:15:51 AM MST, "Joe k1ike_mail@... [LDG-auto-tuners]" <LDG-auto-tuners@yahoogroups.com> wrote: Hello Dwayne,

I was disappointed in the fact that the LDG-600ProII would only tune to a VSWR of 1.7 to 1. I am using the tuner with an Ameritron ALS-600 amplifier at a remote site. At full output of 600 watts, the reflected power of a VSWR of 1.7 to 1 would be 40+ watts. The ALS-600 amplifier wants to see less than 50 watts of reflected power.

This is an excerpt from the ALS-600 amplifier manual:

"If the reflected power exceeds 50 watts the power level should be reduced until the reflected
power indicated on the internal meter is 50 watts or less on peaks. At approximately 75 watts of reflected power the internal safety circuitry will disable the amplifier."

This means that, with a VSWR of 1.7 to 1, I am getting close to a reflected power level that becomes questionable. It becomes more of a concern when the station is sometimes 1,000 miles away and I loose the ability to watch meters. My solution has been to add an Elecraft wattmeter to the station and remotely watch VSWR and power levels. Solid state amplifiers are less forgiving of VSWR than tube amplifiers.

I would like to see the tuner tune to 1.3 to 1 VSWR.

Rick,

If the radio starts to fold back at 1.7 SWR, isn't that exactly where you would want the tuner to start tuning?

If a modern radio starts to fold back at 1.5 SWR or less, that's a radio design issue that should be directed to the radio manufacturer.

From an engineering standpoint, the infinite loop issue when the starting threshold could be set below 1.7 is a complete show stopper (many, many radios were damaged on models that allowed that). The need to have the tuner automatically start tuning at 1.5 or 1.3 is a condition that as the user could press the tune button on the tuner (or radio in some cases) any time they choose.

Is there some confusion on exactly what the starting threshold setting does? It only applies when Auto mode is on and then only when the SWR is near the starting threshold level. A common misconception is that the starting threshold is assumed to be a final SWR target level. The tuner will alway finds the best match that it can, it will never stop early if it finds a 1.5 while tuning.

WK2X,

I apologize in advance, but I'm not following the logic. The starting threshold has nothing to do with the final SWR achieved. The tuner only looks at the threshold level as a guide to start tuning when the tuner is in automatic mode. That is, the tuner will only start tuning when the SWR reaches the starting threshold setting of 1.7, 2.0, 2.5, or 3.0. In terms of logic, after the tuner starts, it never looks at the threshold setting again during the entire tuning cycle.

Again, I'm apologizing for not understanding your point, but it really looks like the current configuration of the tuner does exactly what you are asking for.

Dwayne,
Thanks a lot for taking the time to respond to all these questions. I'm sorry if I opened a can of worms with my original question. My error was in mistaking the threshold SWR for the target SWR.

If I now understand you correctly, with the threshold set at 1.7 the tuner views any SWR below 1.7 as "acceptable" and doesn't automatically try to reduce it. The operator can still start a tune cycle to possibly further lower it, but it won't occur automatically. Any SWR at 1.7 or above will trigger an automatic tune with the resultant SWR reduced to the best match the tuner can find. All of this assumes the tuner is in automatic mode of course.

Separately, I really like LDG tuners. Like many hams I live in a neighborhood covered by covenants that exclude a serious antenna. I do well with a 130' OCF dipole, a portion of which sits over the corner of the house. It's a tough antenna to turn into a wide multiband, but my first LDG 600 Pro purchased in 2011 did the trick (and continues to perform flawlessly). I purchased the Pro II to get the metering capability without inserting another element between the amp and the tuner. So far it's been every bit as good as the 600 Pro.

Regards.

John/KC9TND

Rick,

If the radio starts to fold back at 1.7 SWR, isn't that exactly where you would want the tuner to start tuning?<snip>

Yes, but shouldn't the swr go down - not up or stay the same ?

If a modern radio starts to fold back at 1.5 SWR or less, that's a radio design issue that should be directed to the radio manufacturer.

Agreed !

From an engineering standpoint, the infinite loop issue when the starting threshold could be set below 1.7 is a complete show stopper (many, many radios were damaged on models that allowed that). The need to have the tuner automatically start tuning at 1.5 or 1.3 is a condition that as the user could press the tune button on the tuner (or radio in some cases) any time they choose. <snip>

I don't have a problem with it starting the tune cycle at 1.7:1 as if I don't feel that's good enough I can always use the mannual function if need be. Its just the fact that I start a tune cycle and actually see it pass up a 1:1 sometimes several times and then settle on a higher swr. To me, that's not finding the "best match". Which would you say is the better match, a 1:1 or a 2:1 ?

Is there some confusion on exactly what the starting threshold setting does? It only applies when Auto mode is on and then only when the SWR is near the starting threshold level. A common misconception is that the starting threshold is assumed to be a final SWR target level. The tuner will alway finds the best match that it can, it will never stop early if it finds a 1.5 while tuning. <snip>

Again, that's what I've been trying to explain, it doesn't always find the best match and sometimes even makes it worse. So, if I push the tune button and it starts to tune and finds a 1:1 match, but then passes that up and settles on something higher like a 2:1, are you saying that is a better match ? That's the part I find confusing !

Hmmm. That's not what my RT100 appears to do. It is out of service at present, but when I was using it, on tune, the swr meter would hop around, until it completed, very often at an swr level higher than the lowest one observed during that tune cycle. I watched it go right passed 1:1 or nearly so many times. It would select a tune state that gave a satisfactory ratio, 1.7-1.8 etc., but not necessarily the lowest observed in the tune cycle.

Am I misinterpreting this some how?

Dwayne,

I too thank you for clarifying this. I reread the manual and now understand the threshold VSWR value.

But I have another question. When I return to a frequency that I previously used, the tuner uses the previous tuner settings it stored in Memory Tune. What is the threshold for the Memory Tune operation to trigger a re-tune? Is it 1:1 VSWR or something else?

To simplify my question, what value does Memory Tune consider an acceptable VSWR before a re-tune is done?

Joe,

Good question.

All of our tuners have the SWR save threshold set to 3.0. In practice anything that is over 1.7 should not be saved (as has already been discussed), but there is some leeway.

Date: 2017-04-29 01:03:25 UTC
From: steve@...
Topic: 8259 Message: 8259

Two questions:
1) Does anyone know if the M-1000 meter and/or LEDs still function (register power) when the AT-1000 is in pass thru mode. In other words, when the AT-1000 is not adjusting SWR, but simply passing RF on to the antenna.

The reason I ask is I'm wondering if I can use the AT-1000 combo to read power when I have an RT-600 located remotely at the antenna.

Which leads to this question:
2) A bias-T (RC-600) is used to inject DC onto coax center conductor to supply the RT-600. I am assuming this bias-T would need to be on the downstream antenna side (???) of the AT-1000, but is that not problematic itself?

Thanks for any insight. 73 Steve K4SCK

Steve,

Yes, the meter always works with the tuners long as they are both on and connected.

There should be nothing besides coax (and maybe an adapter) between the bias T (RC-600) and the RT-600. Bias T information is in the RT-600 manual from the LDG web site.

If the swr is low enough you do not need an autotuner. Some bands like 80 meters are very difficult to get an antenna to operate over most of the band with a swr low enough the transmitter will not cut back if like most solid state rigs.
If your antenna is , say under 1.5:1 you probably do not need a tuner.

Hi all , this AT100 has been great , but i have noticed a quirk too .
I have the AT100 to turn on when the radio turns on by having it plugged into the accessory socket (applies 13vdc when the radio comes on)

Not every-time does the AT100 turn on , like 1 in 5 times its erratic , i have to reboot the radio (turn off then on) , i have checked and the +v is always behaving as it should from the radio .

Should i place a electrolytic of some size? (500/1000uF) across the DC input of the AT-100 to do some smoothing?

Any more suggestions? (one can see if the AT100 turns on by the lights flashing quickly , as mentioned there is nothing sometimes , all connections are good and reliable)

Sorry for long post , Paul ....

John:

The only way for an LDG tuner to find a solution for a particular frequency is to do so with some transmit power applied, unless of course if the tuner has manual tune controls. Once that solution is found, you can continue to receive taking advantage of the better match. That is until power is removed (unless the tuner has "latching" relays). Changing frequency by a significant amount would require transmit power again to tune to that frequency.

You're correct that this is an advantage of a manual tuner. There are probably ways to use receive level (noise) to automate coming to some decent tuning solution, but I don't know of any tuners that do that. Another way would be for the tuner to have its own (low power) source built in as many analyzers do, but that would require the tuner knowing what frequency it would need to generate.

Sounds like a new product opportunity, marry an antenna analyzer with a light-weight antenna tuner.

"Soon" happened quicker than i thought it was going to .

1st , i did the shotgun effect and retouched all the power in dc stuff with the soldering iron , and added a 330uf before the series diode and after the ferrite bead , no rocket science there as after the series diode is a 7805 5v regulator .

2nd turn on it did it again , got out the scope and measured/looked for a glitch? on the input to the 7805 and output of the 7805 and saw nothing , but i might add that whilst doing all this the AT100 never failed to turn on! ha ha ha .

In a temporary folder named temporary in the Album section here there are screen shots of the input and output of the 7805 at turn on using the scope in capture/one shot mode , not a thing to see there regarding anything unusual , the gap between the top line and bottom line is the turn on voltage with no overshoot or glitches noticeable , this was doing a shot at least 6 times each and those pics are just the common seen.

Then after checking at the +v at the micro-controller itself pins (pins 11/32) nothing to see there either , so looking up the micro-controller a PIC IC and downloading the data sheet I'll read further on , its a big data sheet too .

What do you mean for "receive only"? To give the non resonant antenna a match to the receiver/feedline impedance thus avoiding the signal to be attenuated by mismatch ?

If the antenna is for RX only purpose, a uniformity matching would be better (i.e. a buffer/preamp with few ohms inner impedance) directly at the RX antenna feedpoint, fed via coax cable itself (injector- bias tee).

HELLO....

WHEN USING AN ANTENNA ON A DEDICATED RECEIVER, (old hallicrafters /national)

one must use a manual tuner with capacitance & inductance controls to match the

antenna for the receive frequency (usually by highest signal level/noise)

wouldn't i be nice to have a tuner that would "hear" the signal/noise and do it AUTOMATICALLY)

THATS MY QUESTION , about making an LDG tuner I already have , do it

john

I’d like my car to fly too but it wasn’t designed to do that. It would need wings at least just as the auto tuner would need an RF source. I know that you don’t want to use a manual tuner but if I were doing it I would use a manual tuner with a noise bridge such as the old Heathkit HD-1422 or the MFJ-202(B).

Or , like those newer flash antenna analyzers work , a really low level injection signal and that measures the match and then that thing uses that data to tune or match the Radio/Antenna network , auto tuner/matcher .

Push 1 button and bingo , change bands (say from 30m SW) to 19m SW and push a button , connectors/balun for long wire and coax fed / vertical .

LDG , you can doooooooooo it :_)

Short Wave Listeners will be delighted , me too , Paul

Apologies for being a bit monologue here .

Someone might be interested ?, after reading the linked data sheet for the micro-controller a bit , if one looks at chapter 4 on the left , Reset , then POR and MCLR , power on reset and then the rest of the stuff it looks like everything is inside the IC with Code , magic stuff .
I'll take a look at pin 1 when the cover is off again (its in use atm) , as pin 1 seems important for power on stuff .
Thats all for now , Paul

BTW> sticker on IC , is product name then "10" , version 10?

I would say that it would be possible to make an automatic antenna tuner for a receiver. Whether it would be practical or profitable to manufacture is another question......

Way back in the 1970's I used a Palomar Noise Bridge to tune my multi-band antenna. The noise bridge was placed in series with the coax, between the transceiver and the antenna tuner. You would then tune the receiver to the frequency that you wanted to use and tune the antenna tuner for minimum, or null, noise in the receiver loudspeaker.

It would be technically possible for an automatic antenna tuner to tune for minimum noise instead of minimum VSWR, but would require a cable to feed receiver audio from the receiver to the tuner.

And for a user interface a row of buttons along the front .

120M 90M 75M 60M 49M 41M 31M 25M 22M 19M 16M 13M 11M

M = meter band shortwave , and just press the button

I guess everything would just need to be smd (inductors and the lot) as its just for receiving , also these days IC's can be relays with multiple on 1 IC with plenty of isolation , also a bit of lightning protection for indirect close-ish stuff at the front end (neon and mov type) .

And as previously mentioned the most simplest would be a noise-peaker type of circuit a few posts back (and cheaper) .

Paul

We did an R+D project a few years ago with a DDS chip (low power, serially controlled, agile, RF generator) with LCD display (to show the freq) that produced about 100 mW. Then we interfaced a custom tuner that had a low power SWR sensor.

While that would give you the best SWR match, it would not always protect from adjacent band noise. The switched L-network can only be all pass, low pass or high pass, and never be band pass.

Since most of the modern radios have band pass pre-selectors in them, the only market is really the boat anchors and maybe a few SWL receivers. With extra components needed for the generator and more capacitors to make a T-network to create the desired bandpass, it would almost double the price of a regular tuner.

We've been on the lookout for someone to write it up in QEX, but nothing yet. Maybe someone will do a Raspberry PI implementation.

I would think that a 100mw Rf source would be considered an emitter by the FCC requiring licensing for operation. This may be a problem for something an SWL uses for tuning an antenna.

We picked 100 mW because it's allowed in the US under Part 95. Outside of US may have different rules.

I would like to add that today I tired switching to AM mode when the static happens and I heard faint music playing through the static. I spun the VFO and heard it from 33mhz all the way to 55 kHz. I then plugged the antenna directly to the radio and heard nothing. This is weird.

I'd like to take a wild guess as to what is happening.

You like close to an AM broadcast station. The signal is so strong that the tuner is somehow detecting the signal (diodes in the VSWR monitoring circuit?) When you eliminate the tuner the interference goes away because there is no longer anything to detect the signal.

Try listening on the radio using AM, then take another AM broadcast radio and see if you can match the music/talking with the interference that you are getting. If this is the problem, you may end up looking into some type of filter to eliminate AM broadcast interference.

The tuner is in bypass mode when I am on 6 meters.

I found the interfering channel. It's KFSD AM 1450 and the broadcast tower is about 4 miles from my house. It says they broadcast at 1000 watts. Didn't know I lived so close to a radio station.

I don't need the tuner for 6 meters. I just have my 6m antenna plugged into it for the convenience of the built in antenna switch and also seeing the power and SWR display.

I sounds like you need a high pass filter. DX Engineering has the "DLW Associates AM Broadcast Band Brick-Wall High Pass Filters FL1718". This filter would be put between the antenna and the tuner. The bad news is that it costs $195.00

There are probably others, this is just an example of one. The ARRL site has construction plans if you want to try rolling your own.

Did you match the audio up from KFSD with the interference you are hearing? Make sure your on the right path before you go spending money. It sounds like a good hi-pass filter is going to be a way of life for you and ham radio HF operations. I wouldn't cheapen out on the filter.

The problem only exists when l am on 6 meters, never had a issue on HF which I think is weird.

I did match the audio from the AM station with another radio and I am 100% sure that is where it's coming from.

Since the problem only occurs on 6 meters when my antenna is plugged into the tuner and goes away when plugged directly to the radio. I was thinking about running a duplexer to split HF and 6m. I could run the HF side of the duplexer to the tuner and the VHF side straight to my 6m antenna. Not sure if I an going to like all the added connections.

Ryan,
There are many circuits on the internet to filter out the broadcast band that use 2 or 3 parts. Just do a search. You could probably build one for less than $10 to $15. 73 Mike KF6KXG
